	Index	165

Welcome to the documentation page for **geoh5py**!

IN SHORT

The **geoh5py** library has been created for the manipulation and storage of a wide range of geoscientific data (points, curve, surface, 2D and 3D grids) in **geoh5 file format**. Users will be able to directly leverage the powerful visualization capabilities of **Geoscience ANALYST** along with open-source code from the Python ecosystem.

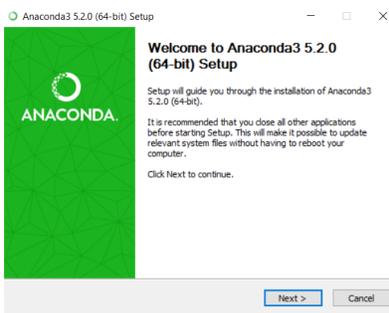

CONTENTS:

2.1 Installation

geoh5py is currently written for Python 3.7 or higher, and depends on **NumPy** and **h5py**.

Note: Users will likely want to take advantage of other packages available in the Python ecosystem. We therefore recommend using **Anaconda** to manage the installation.

Install **geoh5py** from PyPI:

```
$ pip install geoh5py
```

To install the latest development version of **geoh5py**, you can use **pip** with the latest GitHub development branch:

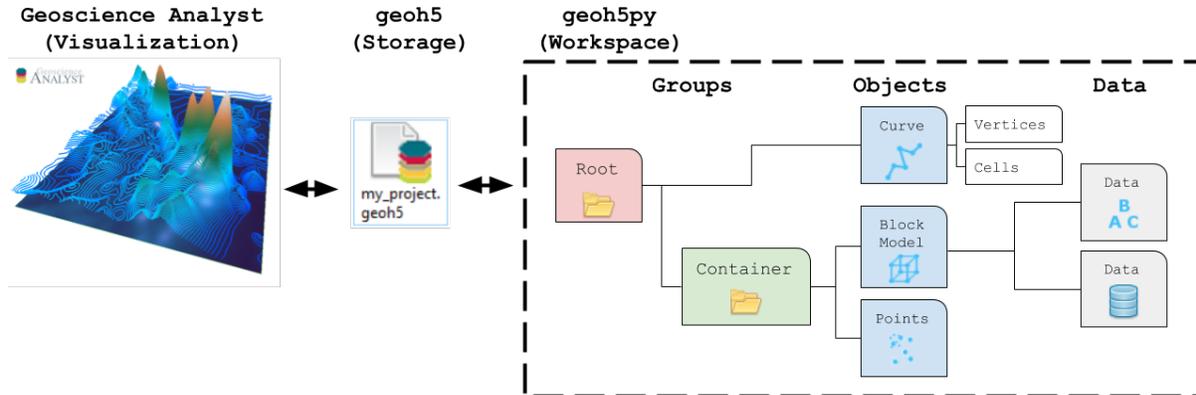

```
$ pip install git+https://github.com/MiraGeoscience/geoh5py.git
```

To work with **geoh5py** source code in development, install from GitHub:

```
$ git clone --recursive https://github.com/MiraGeoscience/geoh5py.git
$ cd geoh5py
$ python setup.py install
```

2.2 Tutorials

This section provides information on how to use the **geoh5py** package, from the creation of a *Workspace* to the creation and manipulation of Entities

2.2.1 Workspace

The core element of a project is the *Workspace*. A project *Workspace* holds core information about the author, version and all entities stored in the geoh5 file. It also knows how to create the core structure needed by *Geoscience ANALYST* for visualization.

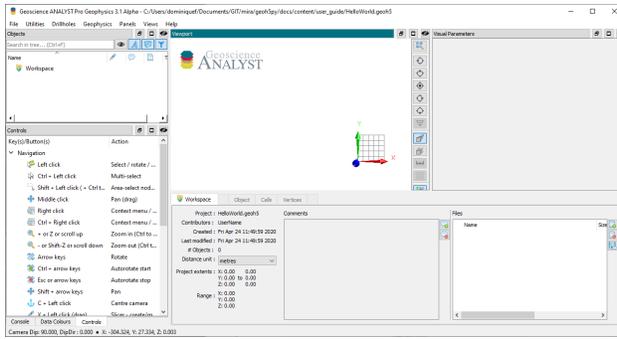

Open and close

You can either open an existing project or create a new project by simply entering the desired file name.

```
[1]: from geoh5py.workspace import Workspace

# Create a new project
workspace = Workspace("my_project.geoh5")
```

Et voila!

By default, the *.geoh5 file is accessed in “read-write” mode. In the eventuality that the file is already used by Geoscience ANALYST, the mode gets changed to “read-only”. This prevents users from modifying the file while used in an active session, but still allows them to extract data from the workspace. The same restriction does not apply to multiple python processes, as permitted by the Single Writer Multiple Reader (SWMR) feature of HDF5.

```
[2]: print(workspace.geoh5)
<HDF5 file "my_project.geoh5" (mode r+)>
```

After completing the read/write process, the workspace must be closed in order to release the file. Geoscience ANALYST does not allow reading on an opened file.

```
[3]: workspace.close()
print(workspace._geoh5)
None
```

Context manager

Likewise, a workspace can be accessed via a context manager which will handle closing the file at the of a process.

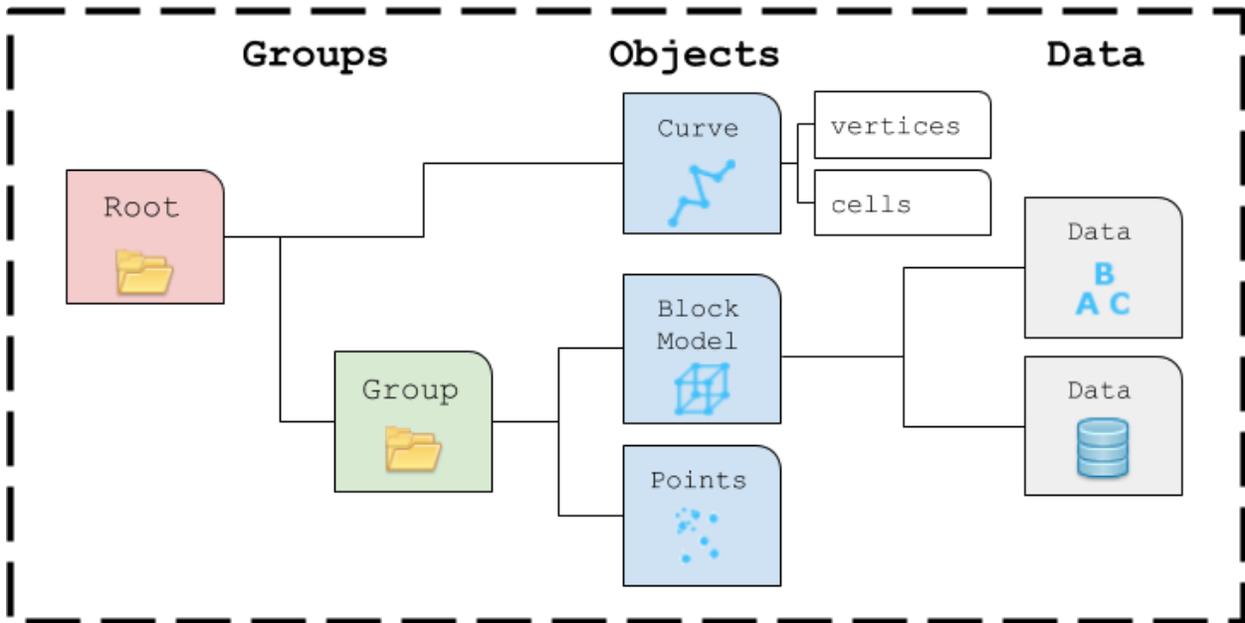

```
[4]: with Workspace("my_project.geoh5") as workspace:
    print(workspace.geoh5)

print(workspace._geoh5)
<HDF5 file "my_project.geoh5" (mode r+)>
None
```

2.2.2 Entities

This section introduces the different entities that can be created and stored in the geoh5 file format.

Workspace

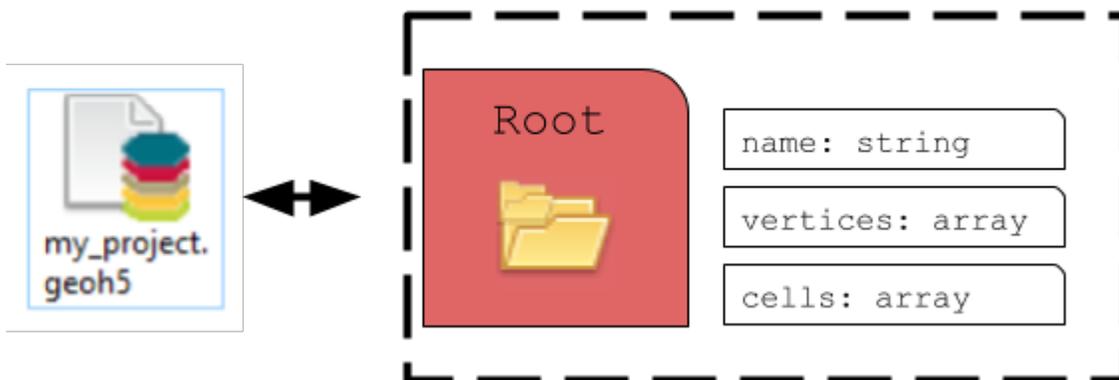

Groups

Groups are effectively containers for other entities, such as Objects (Points, Curve, Surface, etc.) and other Groups. Groups are used to establish parent-child relationships and to store information about a collection of entities.

RootGroup

By default, the parent of any new Entity is the workspace RootGroup. It is the only entity in the Workspace without a parent. Users rarely have to interact with the Root group as it is mainly used to maintain the overall project hierarchy.

Workspace

ContainerGroup

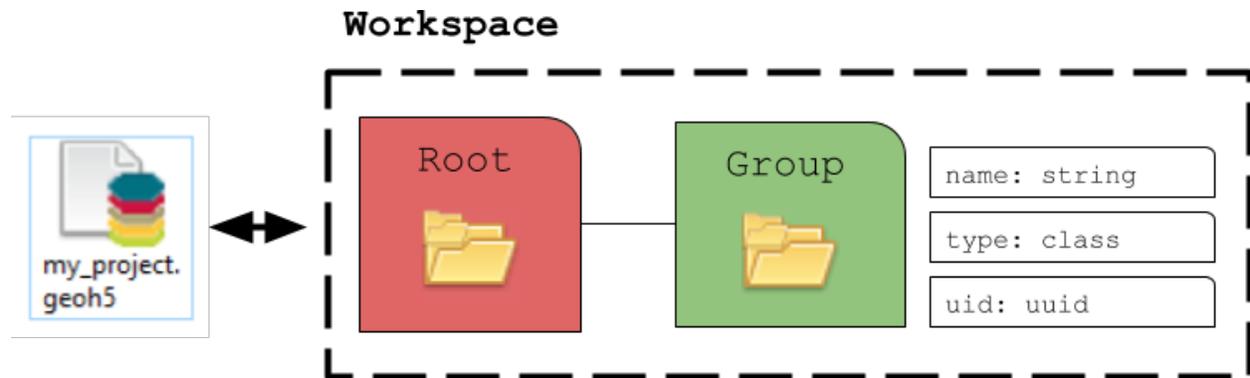

A ContainerGroup can easily be added to the workspace and can be assigned a name and description.

```
[1]: from geoh5py.groups import ContainerGroup
      from geoh5py.workspace import Workspace
      import numpy as np

      # Create a blank project
      workspace = Workspace("my_project.geoh5")

      # Add a group
      group = ContainerGroup.create(workspace, name='myGroup')
```

At creation, "myGroup" is written to the project geoh5 file and visible in the Analyst project tree.

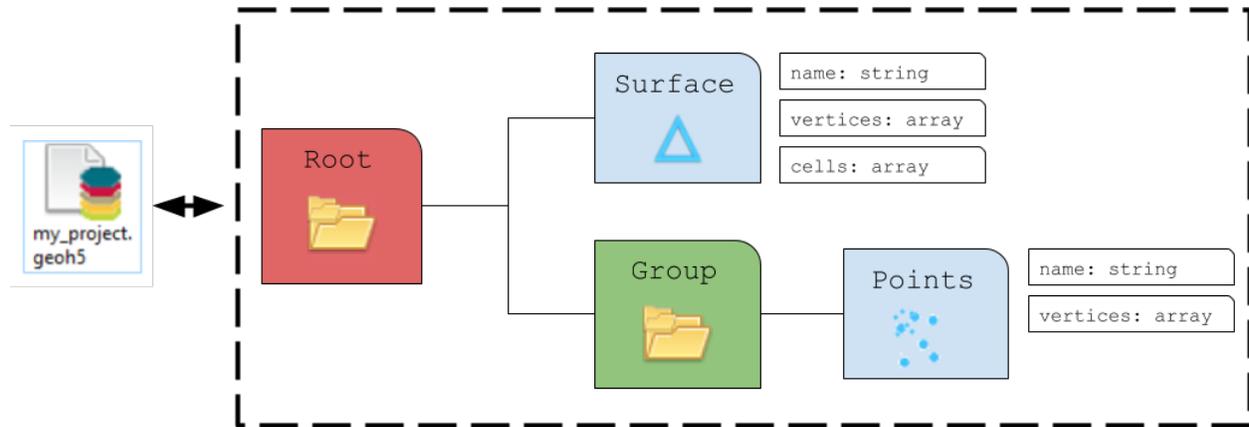

Any entity can be accessed by its name or uid (unique identifier):

```
[2]: print(group.uid)
      print(workspace.get_entity("myGroup")[0] == workspace.get_entity(group.uid)[0])

1cb5e52d-35b5-4cd1-993d-6f553fa213a2
True
```

Objects

The geoh5 format enables storing a wide variety of Object entities that can be displayed in 3D. This section describes the collection of Objects entities currently supported by geoh5py.

Points

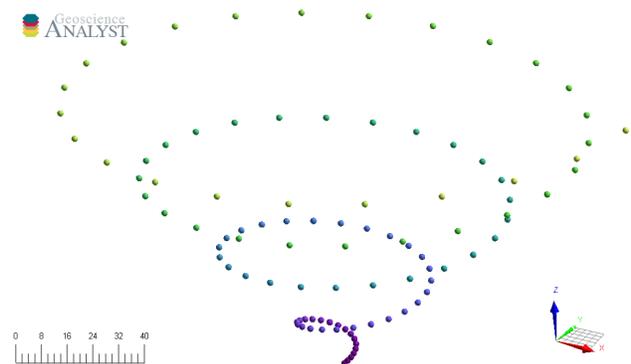

The Points object consists of a list of vertices that define the location of actual data in 3D space. As for all other Objects, it can be created from an array of 3D coordinates and added to any group as follow:

```
[3]: from geoh5py.objects import Points

# Generate a numpy array of xyz locations
n = 100
radius, theta = np.arange(n), np.linspace(0, np.pi*8, n)

x, y = radius * np.cos(theta), radius * np.sin(theta)
z = (x**2. + y**2.)**0.5
xyz = np.c_[x.ravel(), y.ravel(), z.ravel()] # Form a 2D array

# Create the Point object
points = Points.create(
    workspace,      # The target Workspace
    vertices=xyz    # Set vertices
)
```

Curve

The Curve object, also known as a polyline, is often used to define contours, survey lines or geological contacts. It is a sub-class of the Points object with the added `cells` property, that defines the line segments connecting its vertices. By default, all vertices are connected sequentially following the order of the input vertices.

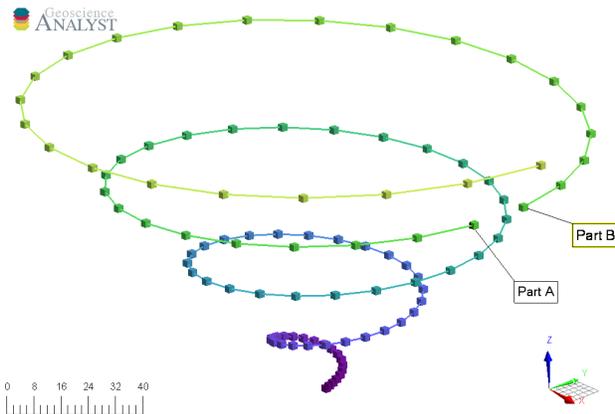

```
[4]: from geoh5py.objects import Curve

# Create the Curve object
curve = Curve.create(
    workspace,      # The target Workspace
    vertices=xyz
)
```

Alternatively, the `cells` property can be modified, either directly or by assigning parts identification to each vertices:

```
[5]: # Split the curve into two parts
part_id = np.ones(n, dtype="int32")
part_id[:75] = 2

# Assign the part
curve.parts = part_id
```

Drillhole

Drillhole objects are different from other objects as their 3D geometry is defined by the collar and surveys attributes. As for version geoh5 v2.0, the drillholes require a `DrillholeGroup` entity to store the geometry and data.

```
[6]: from geoh5py.groups import DrillholeGroup
from geoh5py.objects import Drillhole

dh_group = DrillholeGroup.create(workspace)

# Create a simple well
total_depth = 100
dist = np.linspace(0, total_depth, 10)
```

(continues on next page)

(continued from previous page)

```

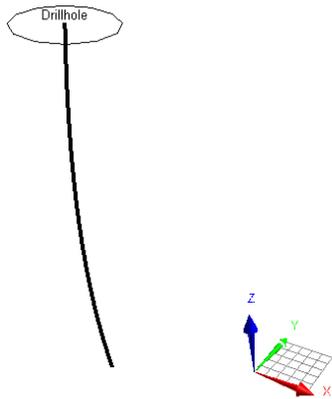

azm = np.ones_like(dist) * 45.
dip = np.linspace(-89, -75, dist.shape[0])
collar = np.r_[0., 10., 10]

well = Drillhole.create(
    workspace, collar=collar, surveys=np.c_[dist, azm, dip], name="Drillhole", parent=dh_
    ↪group
)

print(well.name)

```

Drillhole

Surface

The Surface object is also described by vertices and cells that form a net of triangles. If omitted on creation, the cells property is calculated using a 2D `scipy.spatial.Delaunay` triangulation.

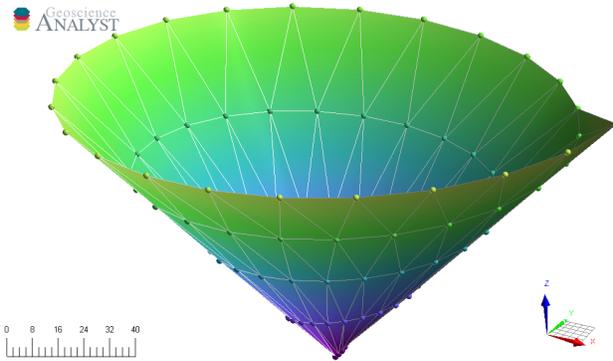

```

[7]: from geoh5py.objects import Surface
      from scipy.spatial import Delaunay

      # Create a triangulated surface from points
      surf_2D = Delaunay(xyz[:, :2])

      # Create the Surface object
      surface = Surface.create(
          workspace,
          vertices=points.vertices, # Add vertices
          cells=surf_2D.simplices
      )

```

GeoImage

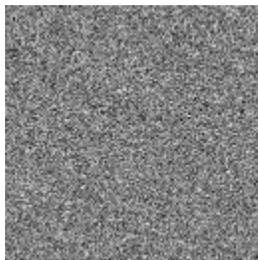

The GeoImage object handles raster data, either single or 3-band images.

```
[8]: from geoh5py.objects import GeoImage
```

```
geoimage = GeoImage.create(workspace)
```

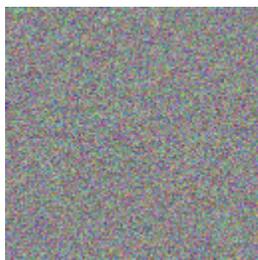

Image values can be assigned to the object from either a 2D numpy.ndarray for single band (gray):

```
[9]: geoimage.image = np.random.randn(128, 128)
display(geoimage.image)
```

or as 3D numpy.ndarray for 3-band RGB image:

```
[10]: geoimage.image = np.random.randn(128, 128, 3)
display(geoimage.image)
```

or directly from file (png, jpeg, tiff).

```
[11]: geoimage.image = "./images/flin_flin_geology.jpg"
```

A PIL .Image object gets exposed to the user, which can be used for common raster manipulation (rotation, filtering, etc). The modified raster is stored back on file as a blob (bytes).

```
[12]: display(geoimage.image)
```

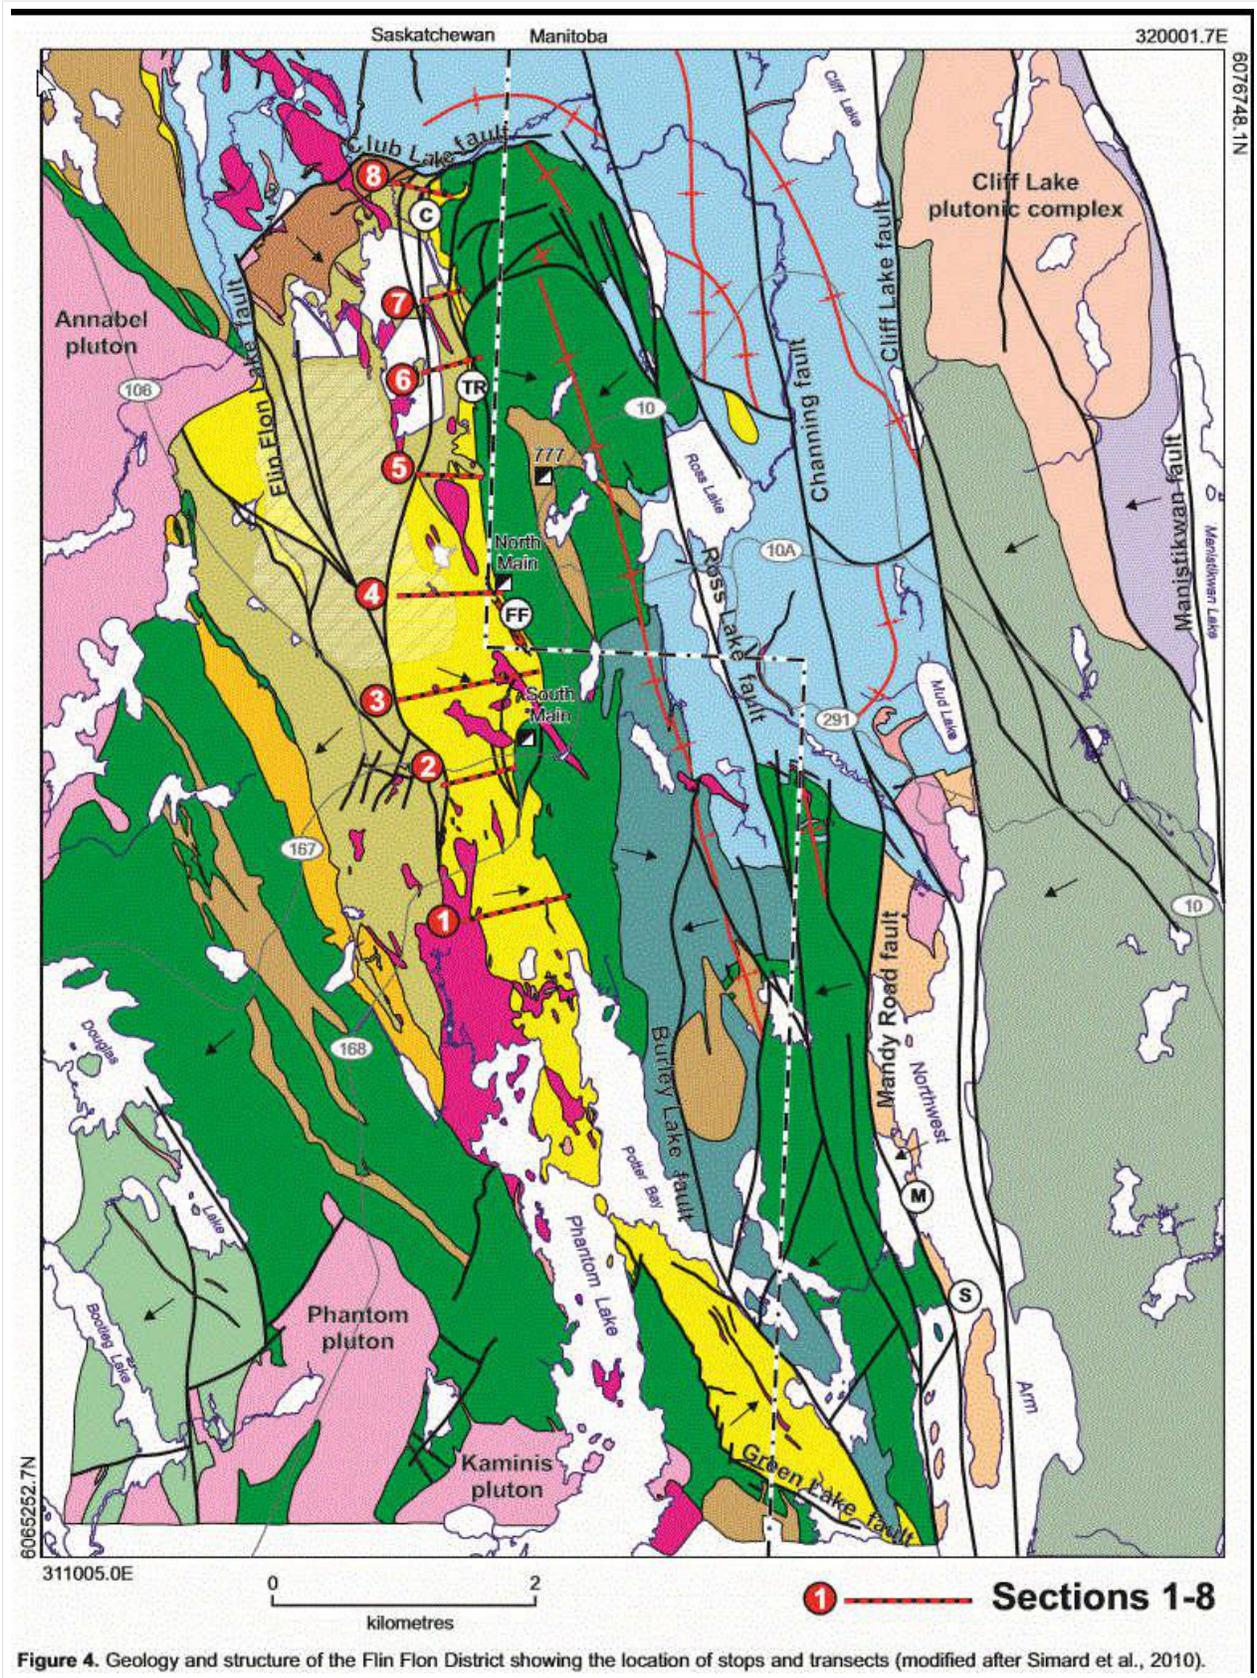

Figure 4. Geology and structure of the Flin Flon District showing the location of stops and transects (modified after Simard et al., 2010).

Geo-referencing

By default, the `GeoImage` object will be displayed at the origin (xy-plane) with dimensions equal to the pixel count. The utility function `GeoImage.georeference` lets users geo-reference the image in 3D space based on at least three (3) input reference points (pixels) with associated world coordinates.

```
[13]: pixels = [
        [18, 73],
        [757, 1014],
        [18, 1014],
    ]
    coords = [
        [311005, 6065252, 0],
        [320001, 6076748, 0],
        [311005, 6076748, 0]
    ]

    geotime.georeference(pixels, coords)
    print(geotime.vertices)

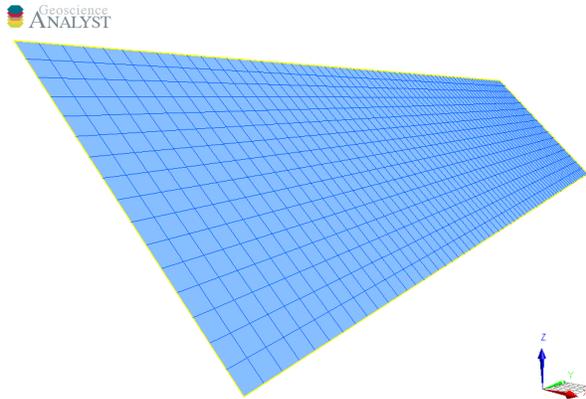

[[ 310785.88227334 6077065.63655685    0.    ]
 [ 320232.29093369 6077065.63655686    0.    ]
 [ 320232.29093369 6064360.17428268    0.    ]
 [ 310785.88227334 6064360.17428268    0.    ]]
```

Grid2D

The `Grid2D` object defines a regular grid of cells often used to display model sections or to compute data derivatives. A `Grid2D` can be oriented in 3D space using the `origin`, `rotation` and `dip` parameters.

```
[14]: from geoh5py.objects import Grid2D

# Create the Surface object
grid = Grid2D.create(
    workspace,
    origin = [25, -75, 50],
    u_cell_size = 2.5,
    v_cell_size = 2.5,
    u_count = 64,
    v_count = 16,
    rotation = 90.0,
    dip = 45.0,
)
```

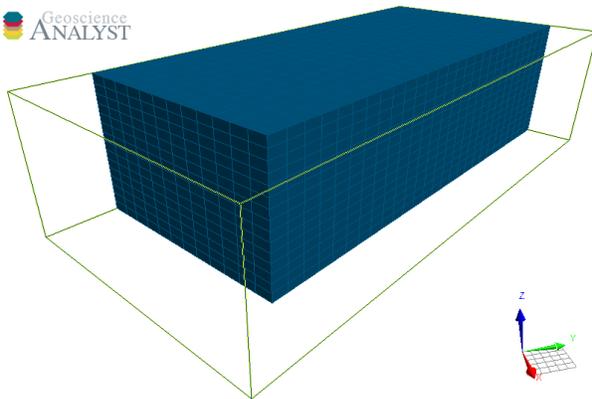

BlockModel

The `BlockModel` object defines a rectilinear grid of cells, also known as a tensor mesh. The cells center position is determined by `cell_delimiters` (offsets) along perpendicular axes (`u`, `v`, `z`) and relative to the origin. `BlockModel` can be oriented horizontally by controlling the `rotation` parameter.

```
[15]: from geoh5py.objects import BlockModel

# Create the Surface object
blockmodel = BlockModel.create(
    workspace,
    origin = [25, -100, 50],
    u_cell_delimiters=np.cumsum(np.ones(16) * 5), # Offsets along u
    v_cell_delimiters=np.cumsum(np.ones(32) * 5), # Offsets along v
    z_cell_delimiters=np.cumsum(np.ones(16) * -2.5), # Offsets along z (down)
    rotation = 30.0
)
```

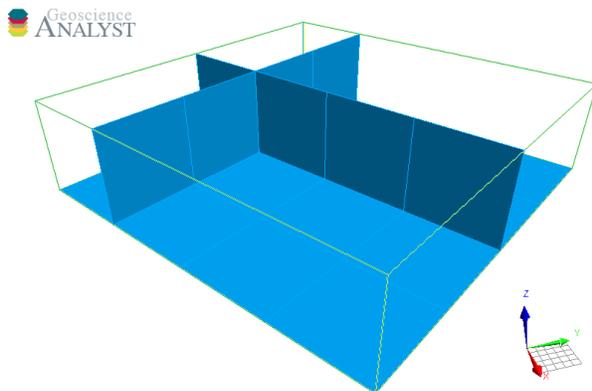

Octree

The Octree object is type of 3D grid that uses a tree structure to define cells. Each cell can be subdivided it into eight octants allowing for a more efficient local refinement of the mesh. The Octree object can also be oriented horizontally by controlling the rotation parameter.

```
[16]: from geoh5py.objects import Octree

octree = Octree.create(
    workspace,
    origin=[25, -100, 50],
    u_count=16,      # Number of cells in power 2
    v_count=32,
    w_count=16,
    u_cell_size=5.0, # Base cell size (highest octree level)
    v_cell_size=5.0,
    w_cell_size=2.5, # Offsets along z (down)
    rotation=30,
)
```

By default, the octree mesh will be refined at the lowest level possible along each axes.

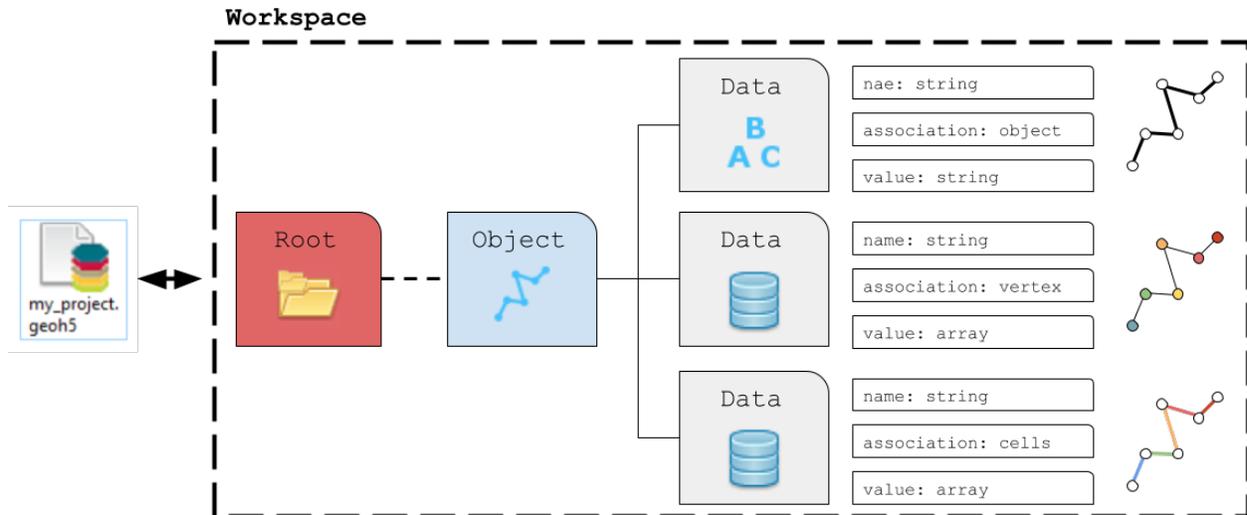

```
[17]: workspace.close()
```

2.2.3 Data

The geoh5 format allows storing data (values) on different parts of an Object. The data types currently supported by geoh5py are

- Float
- Integer
- Text
- Colormap
- Well log

```
[1]: from geoh5py.workspace import Workspace
import numpy as np

# Re-use the previous workspace
workspace = Workspace("my_project.geoh5")

# Get the curve from previous section
curve = workspace.get_entity("Curve")[0]
```

Float

Numerical float data can be attached to the various elements making up object. Data can be added to an Object entity using the `add_data` method.

```
[2]: curve.add_data({
    "my_cell_values": {
        "association": "CELL",
        "values": np.random.randn(curve.n_cells)
    }
})

[2]: <geoh5py.data.float_data.FloatData at 0x7f34e037ced0>
```

The association can be one of:

- OBJECT: Single element characterizing the parent object
- VERTEX: Array of values associated with the parent object vertices
- CELL: Array of values associated with the parent object cells

The length and order of the array of values must be consistent with the corresponding element of association. If the association argument is omitted, geoh5py will attempt to assign the data to the correct part based on the shape of the data values, either `object.n_values` or `object.n_cells`

```
[3]: # Add multiple data vectors on a single call
data = {}
for ii in range(8):
```

(continues on next page)

(continued from previous page)

```

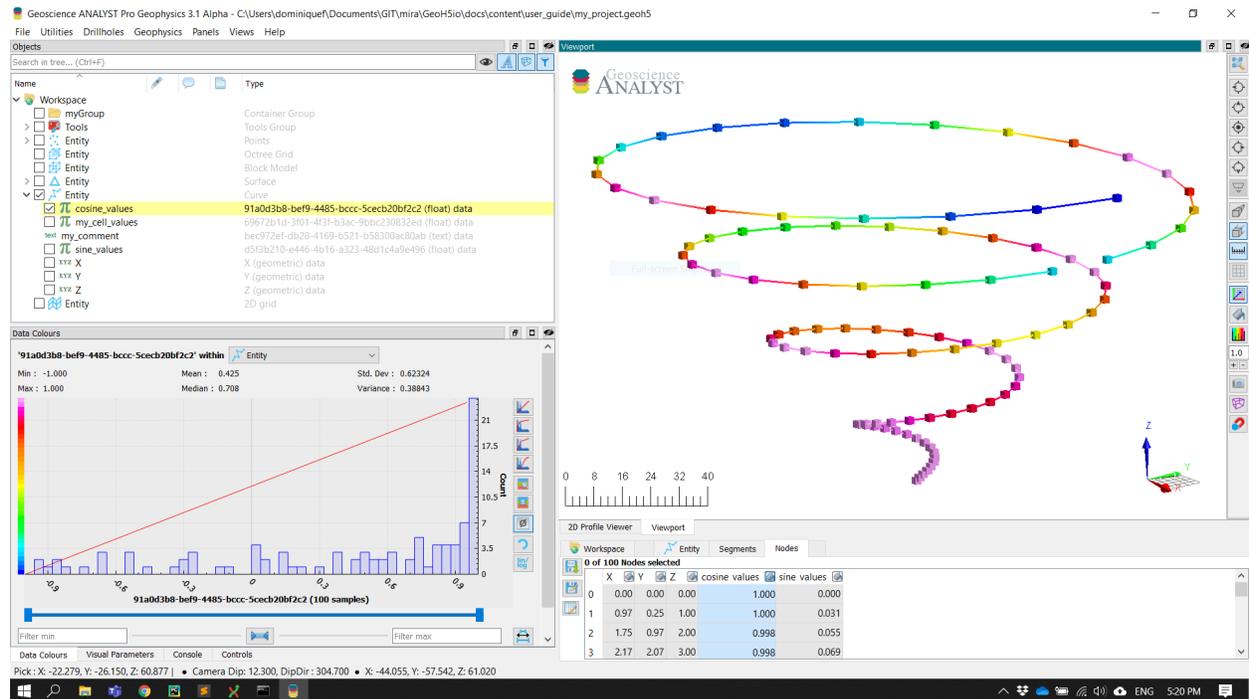

data[f"Period:{ii}"] = {
    "association": "VERTEX",
    "values": (ii+1) * np.cos(ii*curve.vertices[:, 0]*np.pi/curve.vertices[:, 0].
↪max()/4.)
}

data_list = curve.add_data(data)
print([obj.name for obj in data_list])

['Period:0', 'Period:1', 'Period:2', 'Period:3', 'Period:4', 'Period:5', 'Period:6',
↪ 'Period:7']

```

The newly created data is directly added to the project's geoh5 file and available for visualization:

Integer

Same implementation as for *Float* data type but with values provided as integer (int32).

Text

Text (string) data can only be associated to the object itself.

```

[4]: curve.add_data({
    "my_comment": {
        "association": "OBJECT",
        "values": "hello_world"
    }
})

```

```
[4]: <geoh5py.data.text_data.TextData at 0x7f34b42d9690>
```

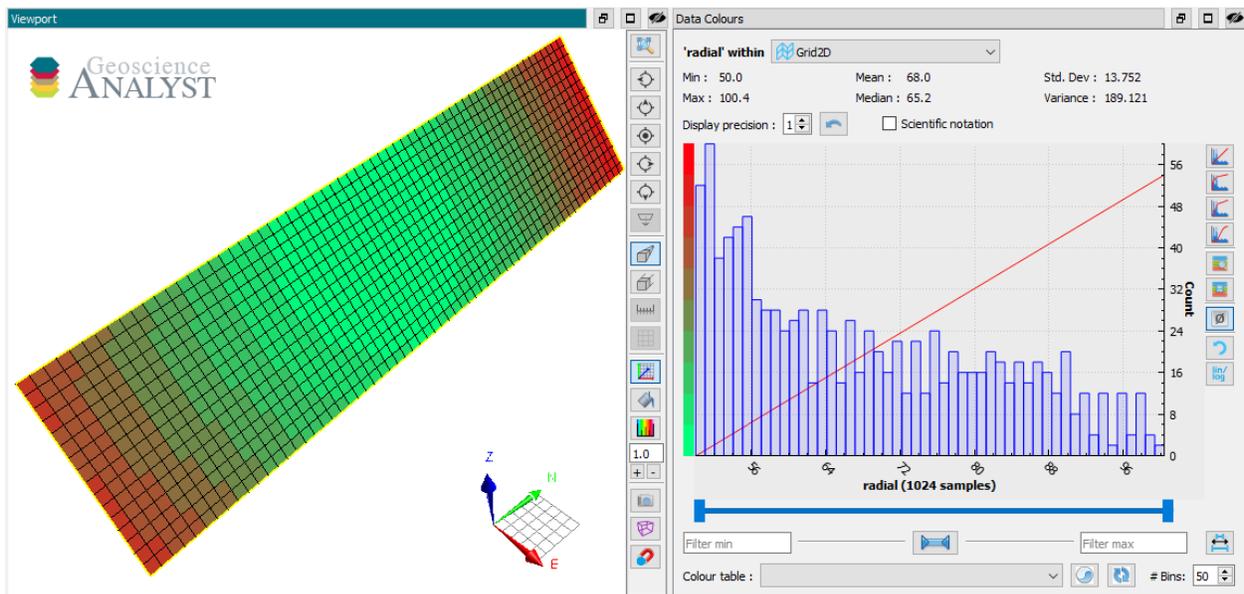

Colormap

The colormap data type can be used to store or customize the color palette used by Geoscience ANALYST.

```
[5]: from geoh5py.data.color_map import ColorMap

# Create some data on a grid2D entity.
grid = workspace.get_entity("Grid2D")[0]

# Add data
radius = grid.add_data({
    "radial": {"values": np.linalg.norm(grid.centroids, axis=1)}
})
```

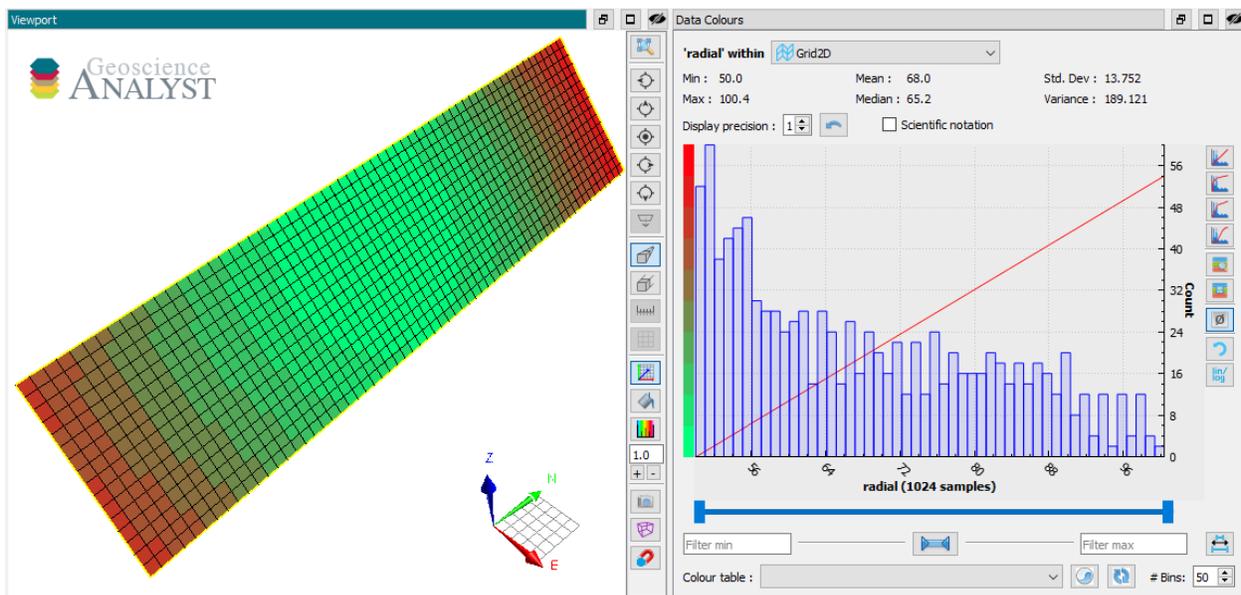

```
[6]: # Create a simple colormap that spans the data range
nc = 10
rgba = np.vstack([
    np.linspace(radius.values.min(), radius.values.max(), nc), # Values
    np.linspace(0, 255, nc), # Red
    np.linspace(255, 0, nc), # Green
    np.linspace(125, 15, nc), # Blue,
    np.ones(nc) * 255, # Alpha,
]).T
```

We now have an array that contains a range of integer values for red, green, blue and alpha (RGBA) over the span of the data values. This array can be used to implicitly create a *ColorMap* from the *EntityType*.

```
[7]: # Assign the colormap to the data type
radius.entity_type.color_map = rgba
```

The resulting ColorMap stores the values to geoh5 as a `numpy.recarray` with fields for Value, Red, Green, Blue and Alpha.

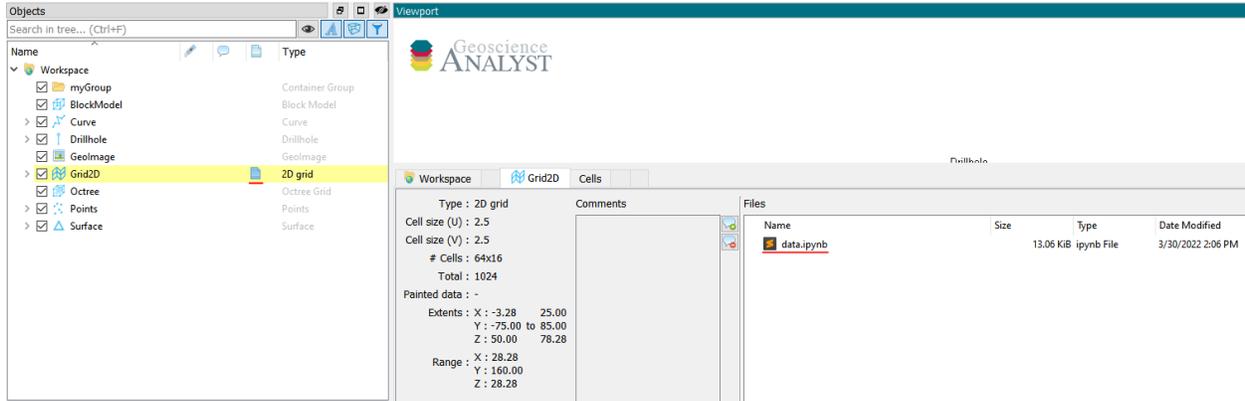

```
[8]: radius.entity_type.color_map._values
[8]: rec.array([( 50.03124024,   0, 255, 125, 255),
 ( 55.62664299,   28, 226, 112, 255),
 ( 61.22204575,   56, 198, 100, 255),
 ( 66.8174485 ,   85, 170,  88, 255),
 ( 72.41285126,  113, 141,  76, 255),
 ( 78.00825401,  141, 113,  63, 255),
 ( 83.60365676,  170,  85,  51, 255),
 ( 89.19905952,  198,  56,  39, 255),
 ( 94.79446227,  226,  28,  27, 255),
 (100.38986503,  255,   0,  15, 255)],
 dtype=[('Value', '<f8'), ('Red', 'u1'), ('Green', 'u1'), ('Blue', 'u1'), ('
 ↪ Alpha', 'u1')])
```

Files

Raw files can be added to groups and objects and stored as blob (bytes) data in geoh5.

```
[9]: file_data = grid.add_file("./data.ipynb")
```

The information can easily be re-exported out to disk with the save method.

```
[10]: file_data.save_file(path="./temp", name="new_name.ipynb")
```

Well Data

In the case of *Drillhole* objects, data are always stored as from-to interval values.

Depth Data

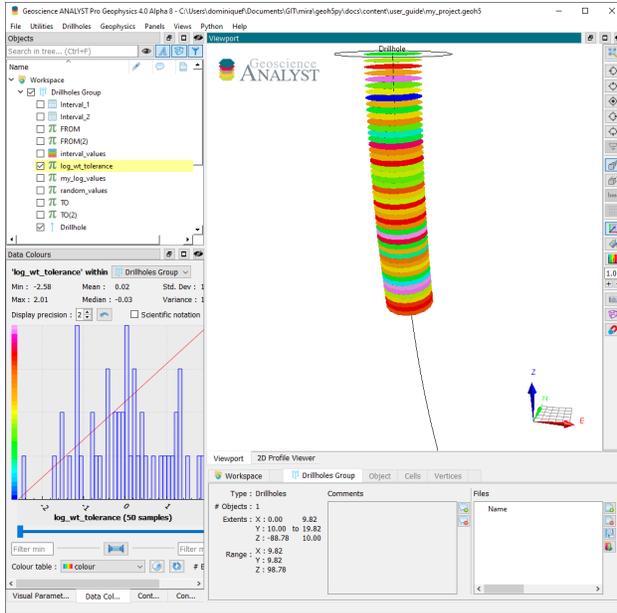

Depth data are used to represent measurements recorded at discrete depths along the well path. A depth attribute is required on creation. Depth markers are converted internally to from-to intervals by adding a small depth values defined by the `collocation_distance`. If the *Drillhole* object already holds depth data at the same location, geoh5py will group the datasets under the same *PropertyGroup*.

```
[12]: well = workspace.get_entity("Drillhole")[0]
depths_A = np.arange(0, 50.) # First list of depth

# Second list slightly offsetted on the first few depths
depths_B = np.arange(0.01, 50.01)

# Add both set of log data with 0.5 m tolerance
well.add_data({
    "my_log_values": {
        "depth": depths_A,
        "values": np.random.randn(depths_A.shape[0]),
    },
    "log_wt_tolerance": {
        "depth": depths_B,
        "values": np.random.randn(depths_B.shape[0]),
    }
})
```

```
[12]: [<abc.FloatDataConcatenated at 0x7f34b2224cd0>,
<abc.FloatDataConcatenated at 0x7f34b222c6d0>]
```

Interval (From-To) Data

Interval data are defined by constant values bounded by a start (FROM) and an end (TO) depth. A from-to attribute defined as a `numpy.ndarray (nD, 2)` is expected on creation. Subsequent data are appended to the same interval `PropertyGroup` if the from-to values match within the collocation distance parameter. Users can control the tolerance for matching intervals by supplying a `collocation_distance` argument in meters, or by setting the default on the drillhole entity (`default_collocation_distance = 1e-2` meters).

```
[13]: # Define a from-to array
from_to = np.vstack([
    [0.25, 25.5],
    [30.1, 55.5],
    [56.5, 80.2]
])

# Add some reference data
well.add_data({
    "interval_values": {
        "values": np.asarray([1, 2, 3]),
        "from-to": from_to,
        "value_map": {
            1: "Unit_A",
            2: "Unit_B",
            3: "Unit_C"
        },
    },
    "type": "referenced",
})

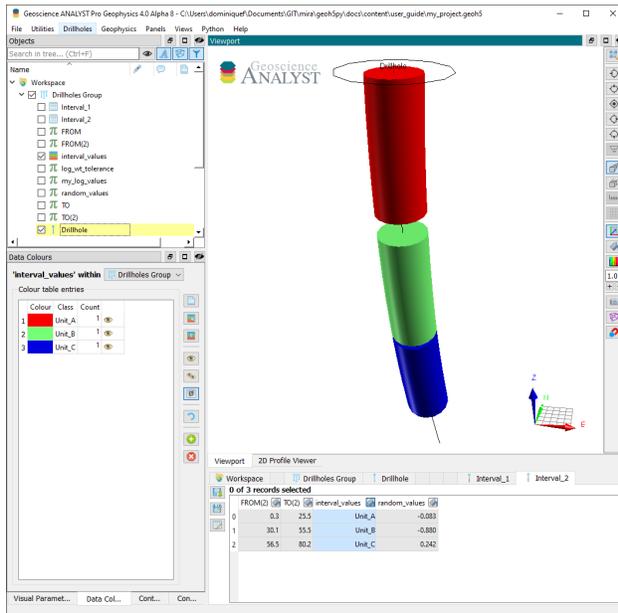

# Add float data on the same intervals
well.add_data({
    "random_values": {
```

(continues on next page)

(continued from previous page)

```
"values": np.random.randn(from_to.shape[0]),
"from-to": from_to,
}
})
```

[13]: <abc.FloatDataConcatenated at 0x7f34b222c8d0>

Get data

Just like any Entity, data can be retrieved from the Workspace using the `get_entity` method. For convenience, Objects also have a `get_data_list` and `get_data` method that focusses only on their respective children Data.

```
[14]: my_list = curve.get_data_list()
print(my_list, curve.get_data(my_list[0]))
```

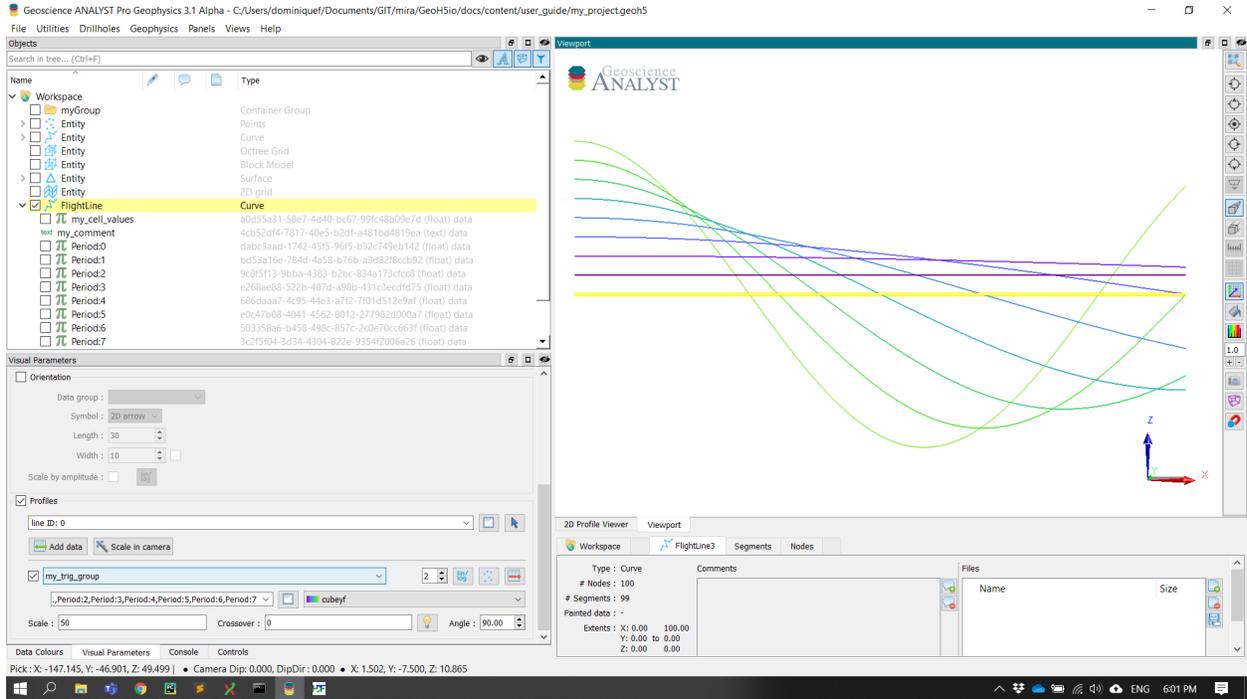

```
['Period:0', 'Period:1', 'Period:2', 'Period:3', 'Period:4', 'Period:5', 'Period:6',
↪ 'Period:7', 'my_cell_values', 'my_comment'] [<geoh5py.data.float_data.FloatData object_
↪ at 0x7f34b427a150>]
```

2.2.4 Property Groups

Data entities sharing the same parent Object and association can be linked within a `property_groups` and made available through profiling. This can be used to group data that would normally be stored as 2D array.

```
[15]: # Add another VERTEX data and create a group with previous
curve.add_data_to_group([obj.name for obj in data_list], "my_trig_group")
```

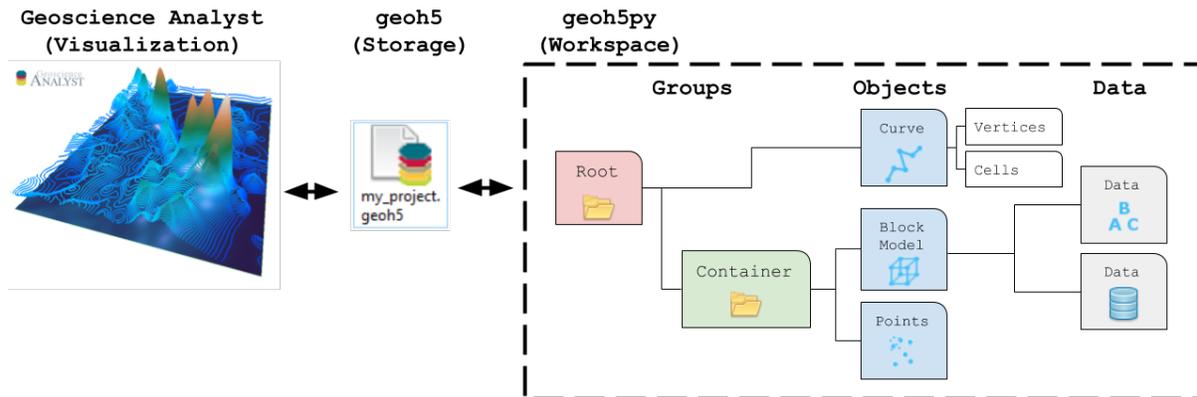

[15]: <geoh5py.groups.property_group.PropertyGroup at 0x7f34b428a410>

[16]: `workspace.close()`

2.2.5 Surveys

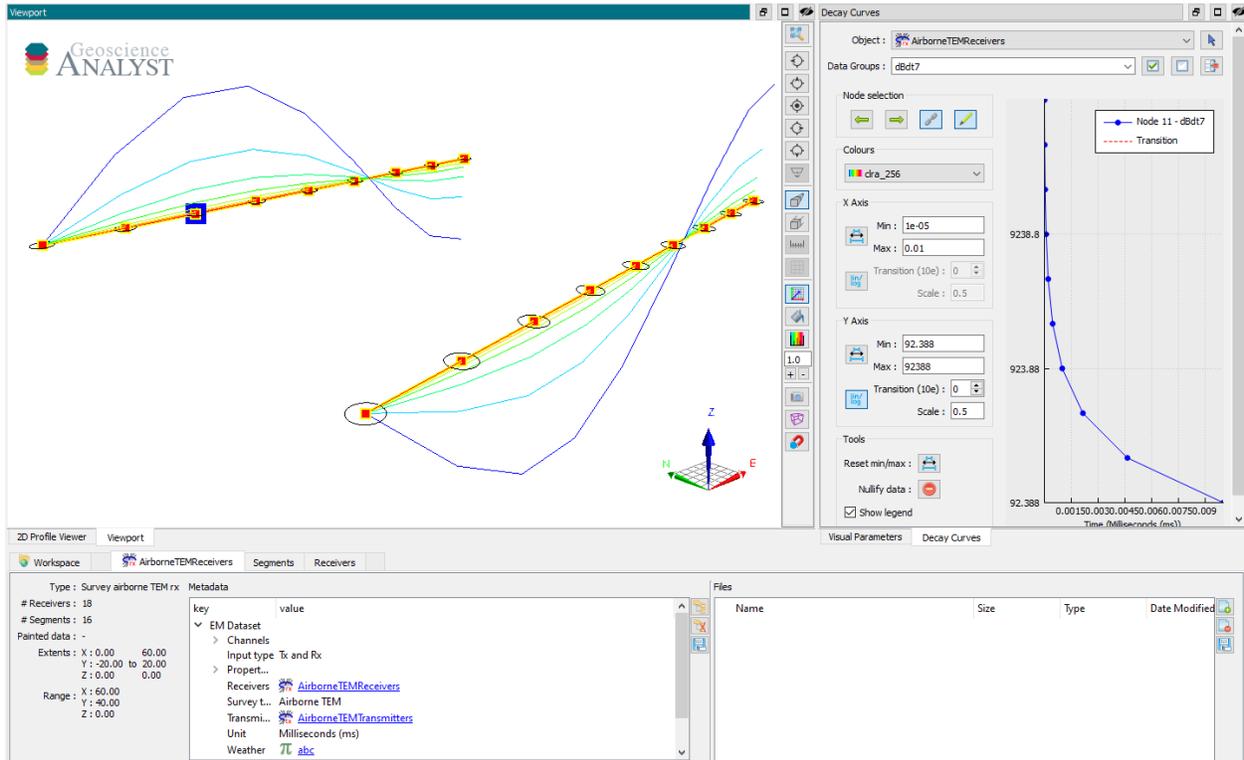

This section provides information on how to create geophysical surveys programmatically.

Airborne Time-Domain

This type of survey can be used to store airborne time-domain electromagnetic (ATEM) data defined by a fixed transmitter-receiver loop configuration. The survey is made up of two entities (*AirborneTEMTransmitters* and *AirborneTEMReceivers*) linked by their metadata.

The following example shows how to generate an airborne TEM survey with associated data stored in geoh5 format and accessible from Geoscience ANALYST.

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import AirborneTEMReceivers, AirborneTEMTransmitters

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_stations = 9
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_stations), np.linspace(-20, 20., n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_stations)).astype('int')

# Create the survey as a coincident loop system
aem_receivers = AirborneTEMReceivers.create(workspace, vertices=vertices, parts=parts)
aem_transmitters = AirborneTEMTransmitters.create(workspace, vertices=vertices,
↳parts=parts)
```

(continues on next page)

(continued from previous page)

We have so far created two separate entities, one for transmitter locations and another for the receivers. In order to finalize the survey, the association must be made between the two entities:

```
[2]: aem_receivers.transmitters = aem_transmitters
```

or equivalently

```
[3]: aem_transmitters.receivers = aem_receivers
```

Only one of the two options above is needed.

Once linked, the two entities will share changes applied to the metadata. For example, changing the `input_type` property on the transmitters yield:

```
[4]: aem_transmitters.input_type = "Tx and Rx"
print(aem_receivers.input_type)
```

```
Tx and Rx
```

Metadata

Along with the survey object itself, the metadata contains all the necessary information to define the geophysical experiment.

```
[5]: aem_receivers.metadata
```

```
[5]: {'EM Dataset': {'Channels': [],
  'Input type': 'Tx and Rx',
  'Property groups': [],
  'Receivers': UUID('84cefd54-bae4-42d9-bb6c-167524da234f'),
  'Survey type': 'Airborne TEM',
  'Transmitters': UUID('984bce2e-8851-46ed-8bc7-2883606535f6'),
  'Unit': 'Milliseconds (ms)'}}
```

Channels

List of time channels at which the data are provided.

```
[6]: aem_receivers.channels = np.logspace(-5, -2, 10) # Simple sweep from 1 to 10 ms
```

Input type

Label defining how the survey was created.

- Rx: Survey defined from the `AirborneTEMReceivers` positions, with the `AirborneTEMTransmitters` added from offsets.
- Tx: Survey defined from the `AirborneTEMTransmitters` position, with the `AirborneTEMReceivers` added from offsets.

- Tx and Rx: Survey defined by both the AirborneTEMTransmitters and theAirborneTEMReceivers positions.

Property groups

List of *PropertyGroups* defining the various data components (e.g. dBzdt, Bz, ...). It is expected that each component contains data channels at all times and in the same order as defined in Channels.

The class method *add_component_data* can help users add data from nested dictionaries. Below is an example using four components:

```
[7]: # Create some simple data
data_fun = lambda t: 1./ t * np.sin(np.pi * (x_loc * y_loc).ravel() / 800.)

# Create a nested dictionary of time data.
data = {
    "dBdt" : {
        f"time[{tt}]": {"values": data_fun(time)} for tt, time in enumerate(aem_
↪receivers.channels)
    }
}

aem_receivers.add_components_data(data)

[7]: [<geoh5py.groups.property_group.PropertyGroup at 0x7f8dc4196810>]
```

Metadata are also updated to reflect the addition of component data.

```
[8]: aem_receivers.metadata
[8]: {'EM Dataset': {'Channels': [1e-05,

```

Data channels associated with each component can be quickly accessed through the *BaseEMSurvey.components* property:

```
[9]: aem_receivers.components['dBdt']
[9]: [<geoh5py.data.float_data.FloatData at 0x7f8dc41ae1d0>,
<geoh5py.data.float_data.FloatData at 0x7f8dc41ec3d0>,
<geoh5py.data.float_data.FloatData at 0x7f8d98135390>,
```

(continues on next page)

(continued from previous page)

```
<geoh5py.data.float_data.FloatData at 0x7f8d98b73490>,
<geoh5py.data.float_data.FloatData at 0x7f8dc41dced0>,
<geoh5py.data.float_data.FloatData at 0x7f8dc4196f10>,
<geoh5py.data.float_data.FloatData at 0x7f8dc41969d0>,
<geoh5py.data.float_data.FloatData at 0x7f8dc4196290>,
<geoh5py.data.float_data.FloatData at 0x7f8dc4196110>,
<geoh5py.data.float_data.FloatData at 0x7f8dc4196990>]
```

Receivers

Generic label used for surveys to identify the receiver entity. References to itself in the case of AirborneTEMReceivers.

Survey type

Static label identifier for Airborne TEM survey type.

Transmitters

Generic label used for surveys to identify the transmitter entity. References to itself in the case of AirborneTEMTransmitters.

Unit

Units for time sampling of the data - must be one of Seconds (s), Milliseconds (ms), Microseconds (us) or Nanoseconds (ns).

Loop radius

Specifies the transmitter loop radius.

Custom fields

Metadata are stored in geoh5 as a json structure allowing for custom data fields to be added to the survey. Information such as flight data, date/time, offsets, etc. can be added as string, float and int.

```
[10]: aem_receivers.edit_metadata({"Weather": "sunny"})
```

|atem_custom|

Alternatively, a uuid.UUID value can be used if the information is to be provided at every survey position.

```
[11]: # Add a new data entry
abc = aem_receivers.add_data({
    "abc": {"values": np.random.randn(aem_receivers.n_vertices)}
})
```

(continues on next page)

(continued from previous page)

```
# Assign the data as 'Weather' metadata
aem_receivers.edit_metadata({"Weather": abc.uid})
```

Geoscience ANALYST will automatically create a link referencing the data field to the entity in the project tree.

|atem_uid|

Reserved keywords

For known metadata, such as flight dynamics (yaw, pitch, roll) and offsets (inline, crossline, vertical) the suffix property and value will get replaced based on the input value:

```
[12]: aem_receivers.yaw = 15.
```

|atem_yaw_value|

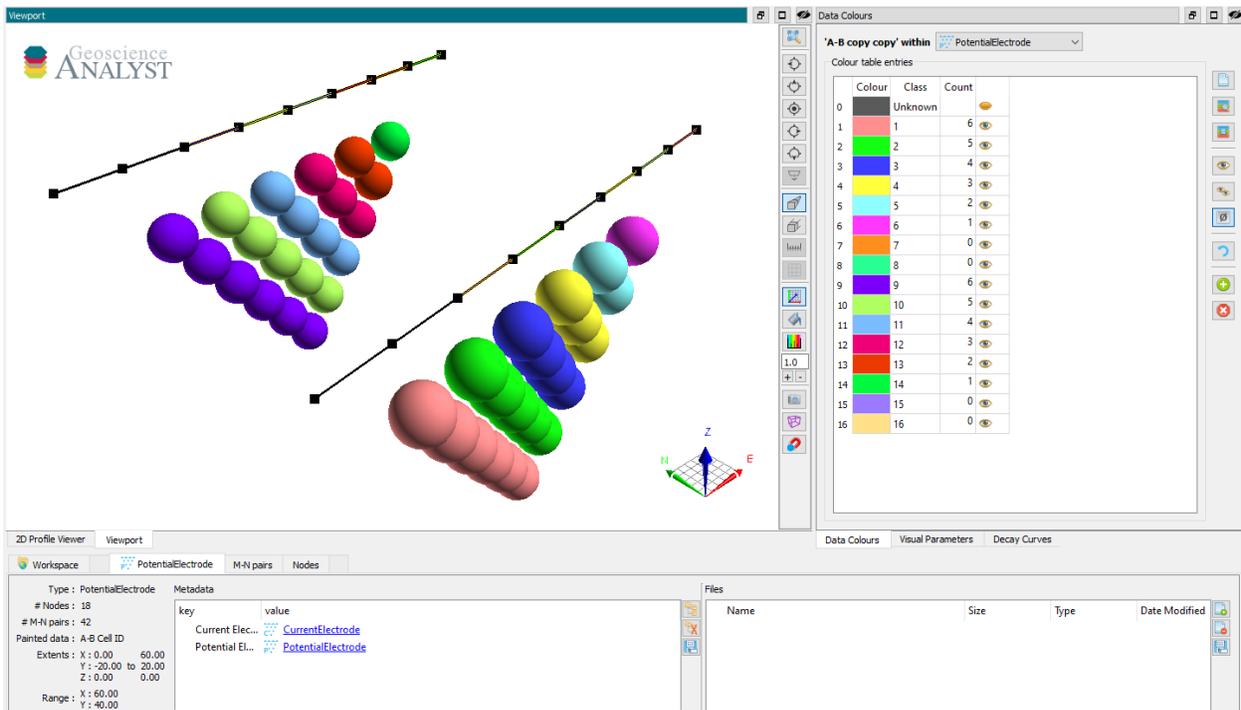

```
[13]: aem_receivers.yaw = abc.uid # Assign to the yaw property
```

|atem_yaw_property|

Direct Current and Induced Polarization (DC-IP)

This survey type is meant to handle direct-current resistivity data. The survey object is made up of two curve entities defining the transmitter (current) and receiver (potential) electrodes.

The following example shows how to generate a DC-IP survey with associated data stored in geoh5 format and accessible from Geoscience ANALYST.

Current Electrode (transmitters)

The *CurrentElectrode* entity defines the A-B dipole pairs used to inject current into the ground. It is a sub-class of the *PotentialElectrode* object defined by vertices (poles) and cells (dipoles). Here we generate four (4) parallel EW lines with eight dipoles per line.

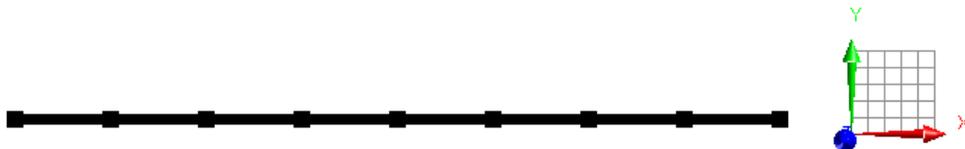

```
[1]: import numpy as np
import uuid
from geoh5py.workspace import Workspace
from geoh5py.objects import CurrentElectrode, PotentialElectrode

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_poles = 9
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_poles), np.linspace(-20, 20., n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_poles)).astype('int')

# Create the CurrentElectrode object
currents = CurrentElectrode.create(workspace, vertices=vertices, parts=parts)
```

At this stage the *CurrentElectrode* object has segments (cells) connecting all poles in series along line.

AB Cell ID

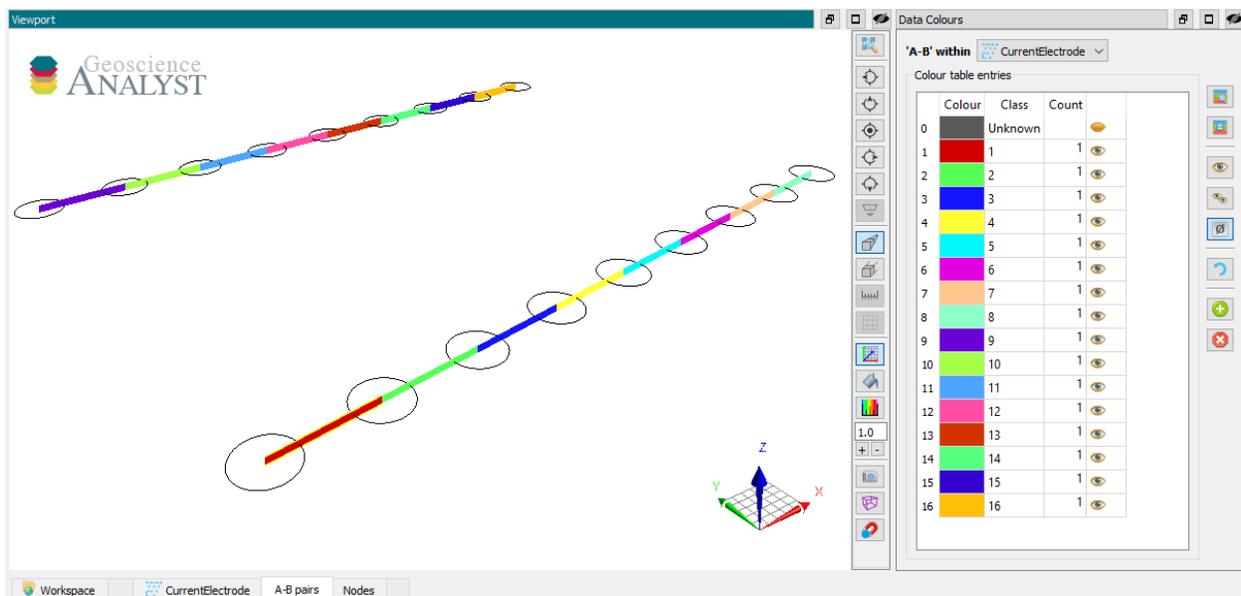

A key element of the DCIP survey objects is the `ab_cell_id` property. This `ReferenceData` contains the map referencing each cell of the `CurrentElectrode` object to a unique A-B source identifier with name.

The utility function `add_default_ab_cell_id` can help generate this map with a simple name string incremator.

```
[2]: currents.add_default_ab_cell_id()
print(currents.ab_cell_id.value_map.map)

{0: 'Unknown', 1: '1', 2: '2', 3: '3', 4: '4', 5: '5', 6: '6', 7: '7', 8: '8', 9: '9',
↪ 10: '10', 11: '11', 12: '12', 13: '13', 14: '14', 15: '15', 16: '16'}
```

In this specific case, every cell on the curve corresponds to a unique dipole source current. For more complex survey configurations, users can edit the cell property in order to define different combinations of connections between poles.

Note: The first entry `{0:Unknown}` is a reserved field used by Geoscience ANALYST to flag unknown data entries.

Potential Electrode (receivers)

The `PotentialElectrode` object defines the M-N dipole pairs used to measure the electric potential (receivers). It is a sub-class of the `Curve` object defined by vertices (poles) and cells (dipoles).

Although poles could be set independently on the `CurrentElectrode` and `PotentialElectrode` objects, here we re-uses the same locations for simplicity:

```
[3]: potentials = PotentialElectrode.create(workspace, vertices=vertices)
```

Next, we must define the receiver dipoles. The following routine generates a maximum of six (6) receivers dipoles per injection currents along line.

```
[4]: N = 6
dipoles = []
current_id = []
```

(continues on next page)

(continued from previous page)

```

for val in currents.ab_cell_id.values: # For each source dipole
    if val == 0: # Skip the unknown
        continue

    cell_id = val - 1 # Python 0 indexing
    line = currents.parts[currents.cells[cell_id, 0]]
    for m_n in range(N):
        dipole_ids = (currents.cells[cell_id, :] + 2 + m_n).astype("uint32") # Skip two
        ↪poles

        # Shorten the array as we get to the end of the line
        if (
            any(dipole_ids > (potentials.n_vertices - 1))
            or any(currents.parts[dipole_ids] != line)
        ):
            continue

        dipoles += [dipole_ids] # Save the receiver id
        current_id += [val] # Save the source id

potentials.cells = np.vstack(dipoles)

```

Finally, users need to create an association between each receiver dipole (M-N) to a dipole current (A-B). The mapping is done through the `ab_cell_id` property of the `PotentialElectrode`. An integer (ID) value must be assigned to each cell, corresponding to the *AB Cell ID* pairs stored on the associated `CurrentElectrode` object.

```
[5]: potentials.ab_cell_id = np.asarray(current_id, dtype="int32")
```

Metadata

The link between the sources *CurrentElectrode* and the receivers *PotentialElectrode* is established by the metadata, shared by both entities. The connection can be made by assigning `current_electrodes` to the receivers:

```
[6]: potentials.current_electrodes = currents
```

or equivalently by setting `potential_electrodes` to the currents

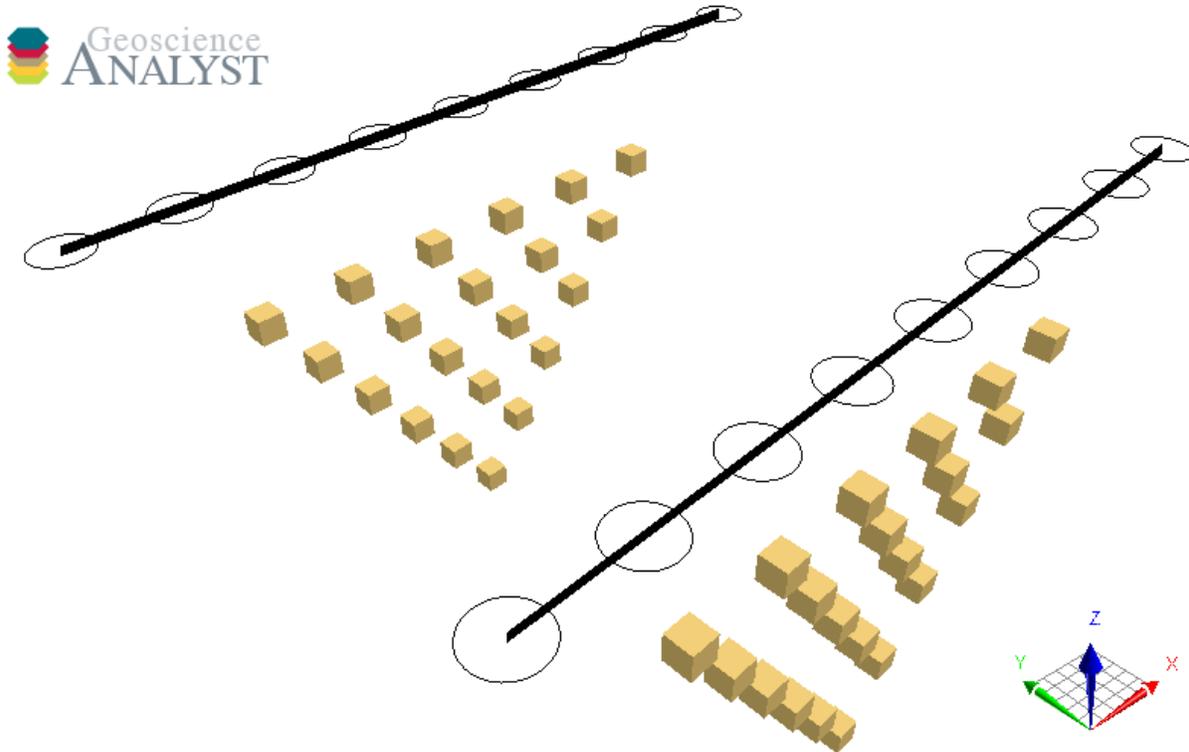

```
[7]: currents.potential_electrodes = potentials
```

In both cases, the link between the two objects gets encoded automatically to their respective metadata.

```
[8]: print(potentials.metadata == currents.metadata)
currents.metadata
```

```
True
```

```
[8]: {'Current Electrodes': UUID('35a58e37-9061-4e78-920f-564becd55e5a'),
      'Potential Electrodes': UUID('3d46b63d-f392-4169-8614-a15360fb7c62')}
```

Note: The `ab_cell_id` property of the `CurrentElectrode` and `PotentialElectrode` are two different `ReferenceData` entities:

```
[9]: print(potentials.ab_cell_id == currents.ab_cell_id)
```

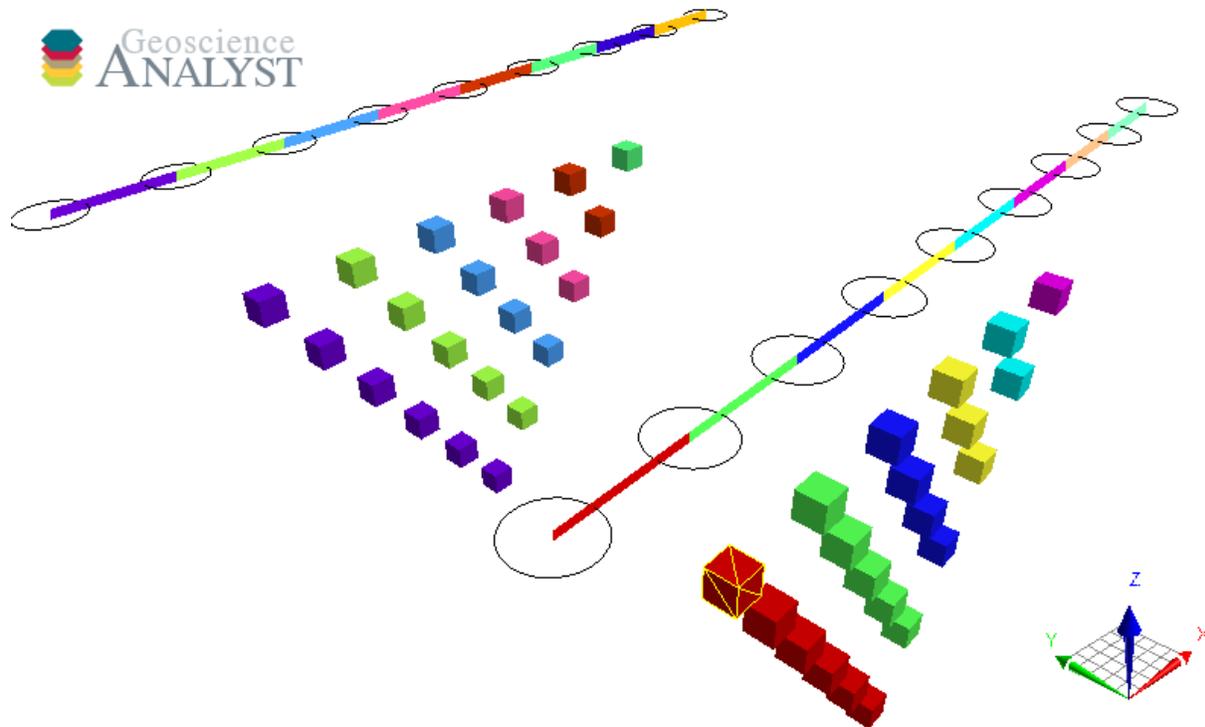

```
False
```

but share the same `DataType` that holds the map of unique source dipoles.

```
[10]: print(potentials.ab_cell_id.entity_type == currents.ab_cell_id.entity_type)
```

```
True
```

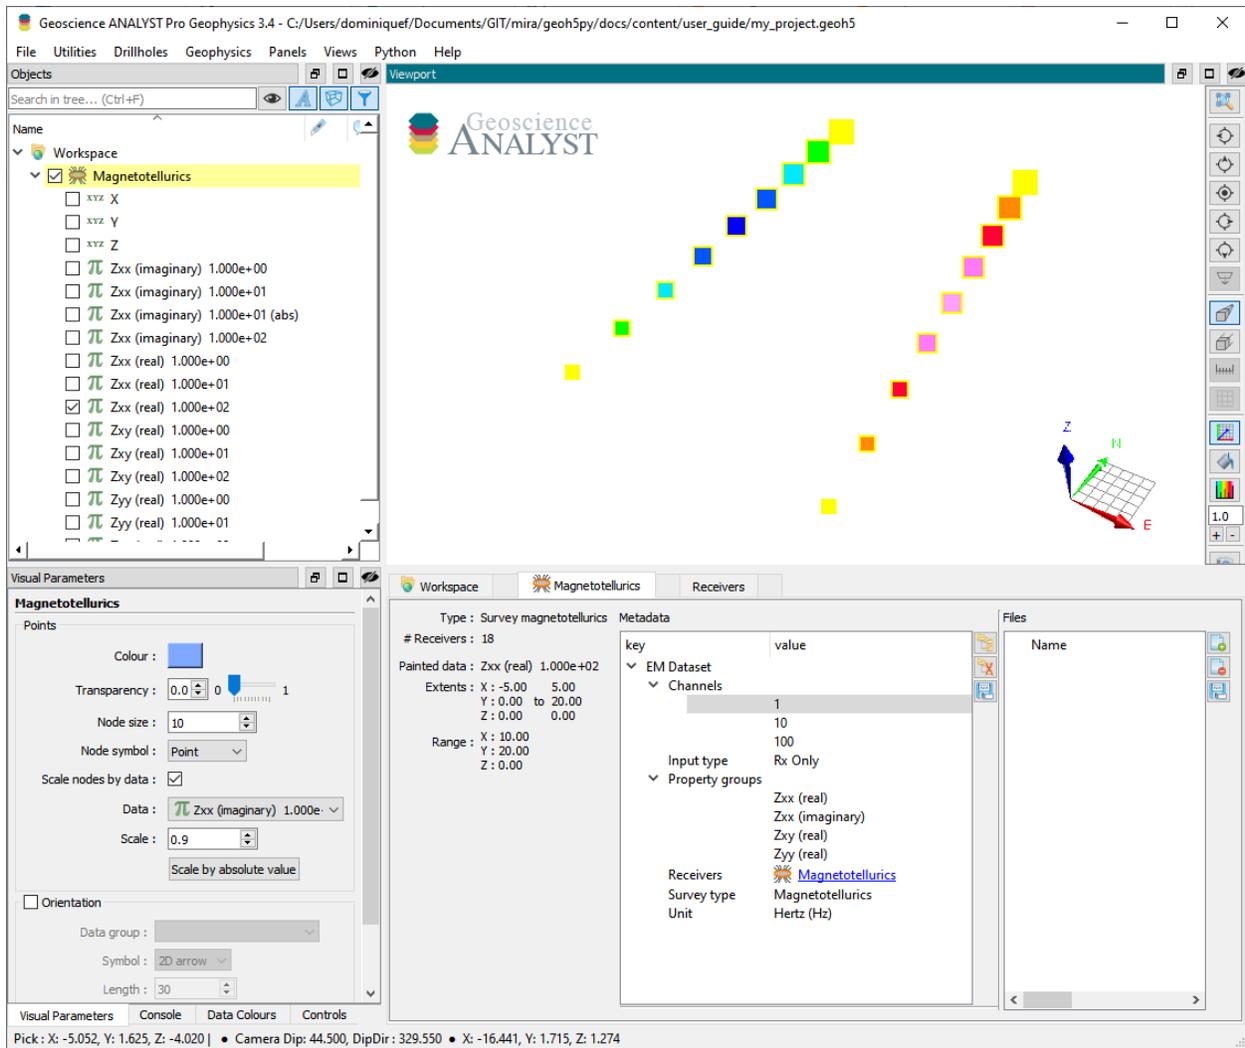

This link between `DataType` allows users to query the data by dipole sources and display the values as pseudo-section in [Geoscience ANALYST](#)

Magnetotellurics

This object can be used to store magnetotelluric (MT) surveys - a natural-source geophysical method. Data are provided in the frequency-domain as point source measurements of either impedances or apparent resistivity/phase.

The following example shows how to generate an MT survey with associated data stored in geoh5 format and accessible from [Geoscience ANALYST](#).

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import MTReceivers

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define a synthetic survey with receivers on 2 lines, 60 m apart
x_loc, y_loc = np.meshgrid(np.linspace(-5, 5, 2), np.linspace(0., 20., 9))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Create the survey from vertices
mt_survey = MTReceivers.create(workspace, vertices=vertices)
```

Only receivers are needed to define the survey as MT uses the ambient electromagnetic field of the Earth - no transmitters (source) required.

Metadata

Along with the *MTReceivers*, the metadata contains all the necessary information to define the geophysical experiment.

```
[2]: mt_survey.metadata
[2]: {'EM Dataset': {'Channels': [],
  'Input type': 'Rx only',
  'Property groups': [],
  'Receivers': UUID('37cab900-5ef8-4a1c-aa99-70215638d238'),
  'Survey type': 'Magnetotellurics',
  'Unit': 'Hertz (Hz)'}}
```

Channels

List of frequencies at which the data are provided.

```
[3]: mt_survey.channels = [1., 10., 100.]
```

Input type

Generic label used in the geoh5 standard for all EM survey entities. Restricted to `Rx only` in the case of natural sources methods.

Property groups

List of *PropertyGroups* defining the various data components (e.g. `Zxx (real)`, `Zxy (imag)`, ...). It is not required to supply all components of the impedance tensor, but it is expected that each component contains a list of data channels of length and in the same order as the `Channels` (one Data per frequency).

The class method `add_components_data` can help users add data from nested dictionaries. Below is an example using four components:

```
[4]: # Arbitrary data generator using sine functions
data_fun = lambda c, f: (c+1.) * np.sin(f * np.pi * (x_loc * y_loc).ravel() / 200.)

# Create a nested dictionary of component and frequency data.
data = {
    component : {
        f"{component}_{freq}": {"values": (ff+1)*1000. + (cc+1) * 100. + np.
↪ arange(vertices.shape[0])} for ff, freq in enumerate(mt_survey.channels)
    } for cc, component in enumerate([
        "Zxx (real)", "Zxx (imaginary)",
        "Zxy (real)", "Zxy (imaginary)",
        "Zyx (real)", "Zyx (imaginary)",
        "Zyy (real)", "Zyy (imaginary)",
    ])
}

mt_survey.add_components_data(data)
```

```
[4]: [<geoh5py.groups.property_group.PropertyGroup at 0x7ff051371d10>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff023797ad0>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff023760490>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff0237623d0>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff023765590>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff023765d50>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff0237606d0>,
<geoh5py.groups.property_group.PropertyGroup at 0x7ff02375bb90>]
```

Metadata are updated immediately to reflect the addition of components:

```
[5]: mt_survey.metadata
```

```
[5]: {'EM Dataset': {'Channels': [1.0, 10.0, 100.0],
'Input type': 'Rx only',
'Property groups': ['Zxx (real)',
'Zxx (imaginary)',
'Zxy (real)',
'Zxy (imaginary)',
'Zyx (real)',
'Zyx (imaginary)',
'Zyy (real)',
'Zyy (imaginary)']},
'Receivers': UUID('37cab900-5ef8-4a1c-aa99-70215638d238'),
'Survey type': 'Magnetotellurics',
'Unit': 'Hertz (Hz)'}]}
```

Data channels associated with each component can be quickly accessed through the *BaseEMSurvey.components* property:

```
[6]: mt_survey.components
```

```
[6]: {'Zxx (real)': [<geoh5py.data.float_data.FloatData at 0x7ff05111c810>,
<geoh5py.data.float_data.FloatData at 0x7ff0237a1b90>,
<geoh5py.data.float_data.FloatData at 0x7ff0237a1150>],
'Zxx (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7ff0500ab890>,
<geoh5py.data.float_data.FloatData at 0x7ff0500afad0>,
<geoh5py.data.float_data.FloatData at 0x7ff023797bd0>],
'Zxy (real)': [<geoh5py.data.float_data.FloatData at 0x7ff023797b50>,
<geoh5py.data.float_data.FloatData at 0x7ff0237603d0>,
<geoh5py.data.float_data.FloatData at 0x7ff023760590>],
'Zxy (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7ff023760d90>,
<geoh5py.data.float_data.FloatData at 0x7ff023762550>,
<geoh5py.data.float_data.FloatData at 0x7ff023762710>],
'Zyx (real)': [<geoh5py.data.float_data.FloatData at 0x7ff023762f50>,
<geoh5py.data.float_data.FloatData at 0x7ff023765710>,
<geoh5py.data.float_data.FloatData at 0x7ff0237658d0>],
'Zyx (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7ff023765ed0>,
<geoh5py.data.float_data.FloatData at 0x7ff023765e10>,
<geoh5py.data.float_data.FloatData at 0x7ff0237650d0>],
'Zyy (real)': [<geoh5py.data.float_data.FloatData at 0x7ff0237652d0>,
<geoh5py.data.float_data.FloatData at 0x7ff023760d50>,
<geoh5py.data.float_data.FloatData at 0x7ff0237604d0>],
'Zyy (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7ff023760d10>,
```

(continues on next page)

(continued from previous page)

```
<geoh5py.data.float_data.FloatData at 0x7ff023760850>,  
<geoh5py.data.float_data.FloatData at 0x7ff02375bb10>]}
```

Receivers

Generic label used in the geoh5 standard for EM survey to identify the receiver entity. Restricted to itself in the case of MTReivers.

Survey type

Label identifier for Magnetotellurics survey type.

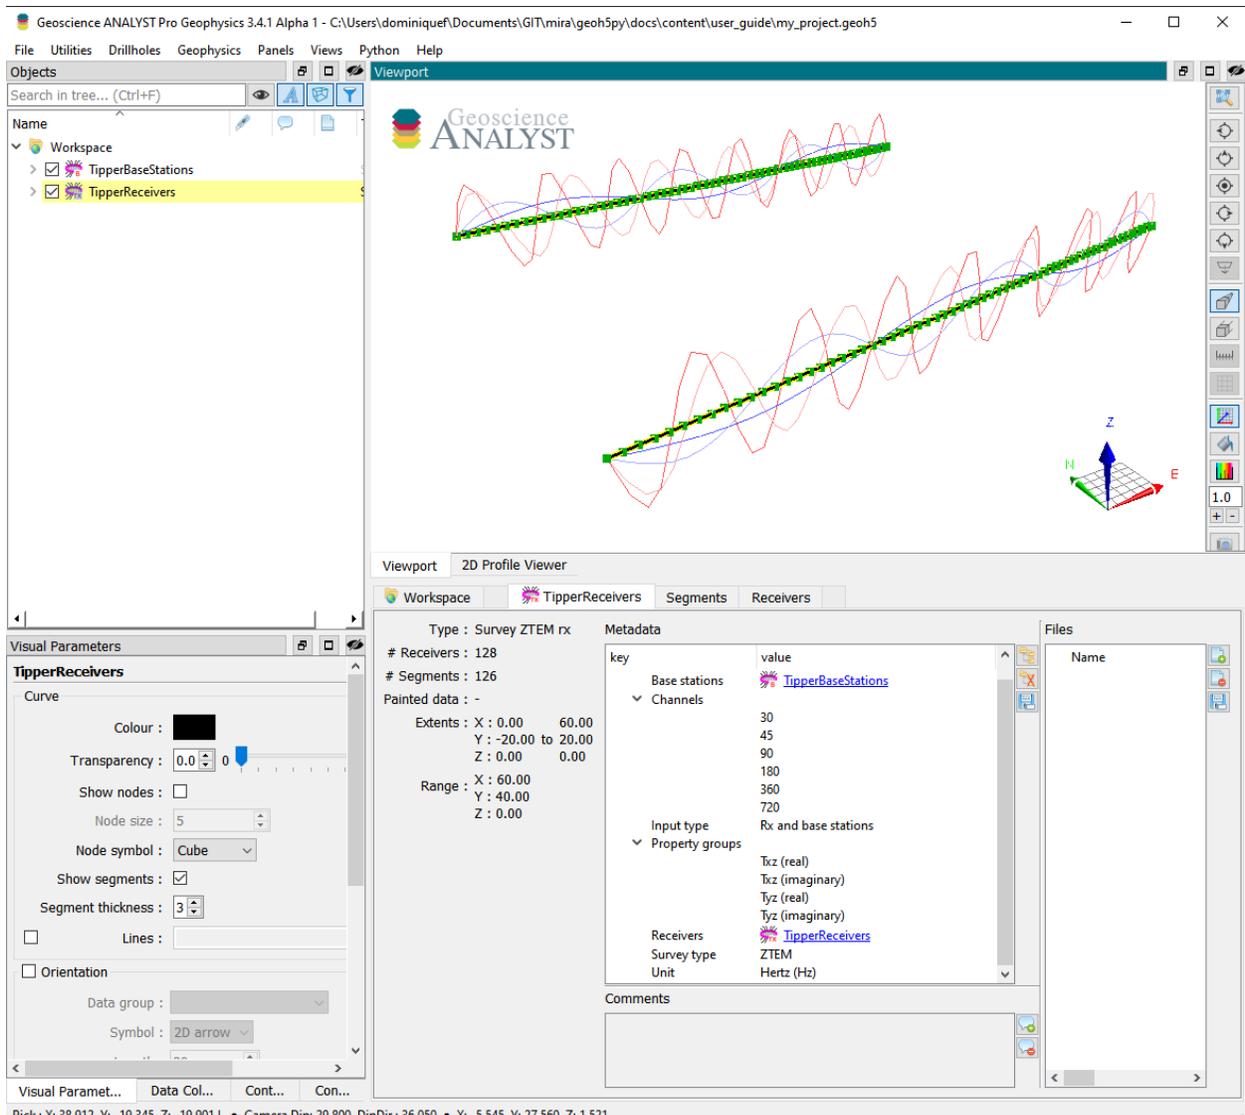

Unit

Units for frequency sampling of the data: Hertz (Hz), KiloHertz (kHz), MegaHertz (MHz) or Gigahertz (GHz).

Tipper

This object can be used to store tipper (ZTEM) surveys - a natural-source geophysical method. Data are provided in the frequency-domain as point source measurements of tipper data.

The following example shows how to generate a tipper survey with associated data stored in geoh5 format and accessible from [Geoscience ANALYST](#).

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import TipperReceivers, TipperBaseStations

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_stations = 64
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_stations), np.linspace(-20, 20., n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_stations)).astype('int')
```

(continues on next page)

(continued from previous page)

```
# Create the survey from vertices
receivers = TipperReceivers.create(workspace, vertices=vertices, parts=parts)
base = TipperBaseStations.create(workspace, vertices=vertices)
```

We have so far created two separate entities, one for the receiver locations and another for the base station(s). In order to finalize the survey, the association must be made between the two entities:

```
[2]: receivers.base_station = base
```

or equivalently

```
[3]: base.receivers = receivers
```

Only one of the two options above is needed.

Metadata

Along with the *TipperReceivers*, the metadata contains all the necessary information to define the geophysical experiment.

```
[4]: receivers.metadata
```

```
[4]: {'EM Dataset': {'Base stations': UUID('52fd43b4-a61e-449a-9ca3-8c859eecceac'),
  'Channels': [],
  'Input type': 'Rx and base stations',
  'Property groups': [],
  'Receivers': UUID('6587cbb3-2856-4db2-b801-1c22e56f0989'),
  'Survey type': 'ZTEM',
  'Unit': 'Hertz (Hz)'}}
```

Channels

List of frequencies at which the data are provided.

```
[5]: receivers.channels = [30., 45., 90., 180., 360., 720.]
```

Input type

Generic label used in the geoh5 standard for all EM survey entities. Restricted to `Rx` and `base station` in the case of a tipper survey.

Property groups

List of *PropertyGroups* defining the various data components (e.g. Txz (real), Tyz (imag), ...). It is not required to supply all components of the impedance tensor, but it is expected that each component contains a list of data channels of length and in the same order as the Channels (one Data per frequency).

The class method *add_components_data* can help users add data from nested dictionaries. Below is an example using four components:

```
[6]: # Arbitrary data generator using sine functions
data_fun = lambda c, f: (c+1.) * (f+1.) * np.sin(f * np.pi * (x_loc * y_loc).ravel() / 400.)

# Create a nested dictionary of component and frequency data.
data = {
    component : {
        f"{component}_{freq}": {"values": data_fun(cc, ff)} for ff, freq in
    enumerate(receivers.channels)
    } for cc, component in enumerate([
        "Txz (real)", "Txz (imaginary)",
        "Tyz (real)", "Tyz (imaginary)",
    ])
}

receivers.add_components_data(data)
```

```
[6]: [<geoh5py.groups.property_group.PropertyGroup at 0x7f9ccc255890>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f9ca322e950>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f9ca31a7310>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f9ccc255910>]
```

Metadata are updated immediately to reflect the addition of components:

```
[7]: receivers.metadata
[7]: {'EM Dataset': {'Base stations': UUID('52fd43b4-a61e-449a-9ca3-8c859eecedac'),
'Channels': [30.0, 45.0, 90.0, 180.0, 360.0, 720.0],
'Input type': 'Rx and base stations',
'Property groups': ['Txz (real)',
'Txz (imaginary)',
'Tyz (real)',
'Tyz (imaginary)'],
'Receivers': UUID('6587cbb3-2856-4db2-b801-1c22e56f0989'),
'Survey type': 'ZTEM',
'Unit': 'Hertz (Hz)'}]}
```

Data channels associated with each component can be quickly accessed through the *BaseEMSurvey.components* property:

```
[8]: receivers.components
[8]: {'Txz (real)': [<geoh5py.data.float_data.FloatData at 0x7f9ccc2a5050>,
<geoh5py.data.float_data.FloatData at 0x7f9ccc2a52d0>,
<geoh5py.data.float_data.FloatData at 0x7f9ca31aacd0>,
<geoh5py.data.float_data.FloatData at 0x7f9ca31aa310>,
```

(continues on next page)

(continued from previous page)

```
values = [
    [V_1, R_1, G_1, B_1, A_1],
    ..., [V_i, R_i, G_i, B_i, A_i]
]
```

where V (Values) are sorted floats defining the position of each RGBA. R (Red), G (Green), B (Blue) and A (Alpha) are integer values between [0, 255].

geoh5py.data.data

```
class geoh5py.data.data.Data(data_type: DataType, **kwargs)
    Bases: Entity
    Base class for Data entities.
    add_file(file: str)
        Alias not implemented from base Entity class.
    property association: DataAssociationEnum | None
        DataAssociationEnum: Relationship made between the values() and elements of the parent object.
        Association can be set from a str chosen from the list of available DataAssociationEnum options.
    property entity_type: DataType
        DataType
    property modifiable: bool
        bool Entity can be modified.
```

property n_values: int | None

int: Number of expected data values based on *association*

abstract classmethod primitive_type() → *PrimitiveTypeEnum*

remove_data_from_group(*data: list | Entity | uuid.UUID | str, name: str = None*)

Remove self from a property group.

property values

Data values

geoh5py.data.data_association_enum

class geoh5py.data.data_association_enum.**DataAssociationEnum**(*value*)

Bases: Enum

Known data association between *values* and the *parent* object. Available options:

CELL = 2

DEPTH = 6

FACE = 4

GROUP = 5

OBJECT = 1

UNKNOWN = 0

VERTEX = 3

geoh5py.data.data_type

class geoh5py.data.data_type.**DataType**(*workspace: workspace.Workspace, **kwargs*)

Bases: *EntityType*

DataType class

property color_map: ColorMap | None

ColorMap: Colormap used for plotting

The colormap can be set from a dict of sorted values with corresponding RGBA color.

```
color_map = {
    val_1: [r_1, g_1, b_1, a_1],
    ...,
    val_i: [r_i, g_i, b_i, a_i]
}
```

classmethod create(*workspace: workspace.Workspace, data_class: type[data.Data]*) → *DataType*

Creates a new instance of *DataType* with corresponding *PrimitiveTypeEnum*.

Parameters

data_class – A *Data* implementation class.

Returns

A new instance of *DataType*.

classmethod `find_or_create(workspace: workspace.Workspace, **kwargs) → DataType`

Find or creates an EntityType with given UUID that matches the given Group implementation class.

Parameters

workspace – An active Workspace class

Returns

A new instance of *DataType*.

classmethod `for_x_data(workspace: workspace.Workspace) → DataType`

classmethod `for_y_data(workspace: workspace.Workspace) → DataType`

classmethod `for_z_data(workspace: workspace.Workspace) → DataType`

property `hidden: bool`

bool: Hidden data [False]

property `mapping: str`

str: Color stretching type chosen from: 'linear', ['equal_area'], 'logarithmic', 'cdf', 'missing'

property `number_of_bins: int | None`

int: Number of bins used by the histogram [50]

property `primitive_type: PrimitiveTypeEnum | None`

PrimitiveTypeEnum

property `transparent_no_data: bool`

bool: Use transparent for no-data-value [True]

property `units: str | None`

str: Data units

property `value_map: ReferenceValueMap | None`

ReferenceValueMap: Reference value map for ReferenceData

The value_map can be set from a dict of sorted values with corresponding str description.

```
value_map = {
    val_1: str_1,
    ...,
    val_i: str_i
}
```

geoh5py.data.data_unit

class `geoh5py.data.data_unit.DataUnit(unit_name: Optional[str] = None)`

Bases: object

Data unit

property `name: str | None`

geoh5py.data.datetime_data

class geoh5py.data.datetime_data.**DatetimeData**(*data_type*: *DataType*, ***kwargs*)

Bases: *Data*

classmethod **primitive_type**() → *PrimitiveTypeEnum*

geoh5py.data.filename_data

class geoh5py.data.filename_data.**FilenameData**(*data_type*: *DataType*, *file_name=None*, ***kwargs*)

Bases: *Data*

property **file_name**: *str* | *None*

str Text value.

classmethod **primitive_type**() → *PrimitiveTypeEnum*

save_file(*path*: *str* = *'./'*, *name=None*)

Save the file to disk.

Parameters

- **path** – Directory to save the file to.
- **name** – Name given to the file.

property values: *bytes* | *None*

Binary *str* value representation of a file.

geoh5py.data.float_data

class geoh5py.data.float_data.**FloatData**(*data_type*: *DataType*, ***kwargs*)

Bases: *NumericData*

Data container for floats values

classmethod **ndv**() → *float*

No-Data-Value

classmethod **primitive_type**() → *PrimitiveTypeEnum*

geoh5py.data.geometric_data_constants

class geoh5py.data.geometric_data_constants.**GeometricDataConstants**

Bases: *object*

classmethod **primitive_type**() → *PrimitiveTypeEnum*

classmethod **x_datatype_uid**() → *UUID*

classmethod **y_datatype_uid**() → *UUID*

classmethod **z_datatype_uid**() → *UUID*

geoh5py.data.integer_data

class geoh5py.data.integer_data.**IntegerData**(*data_type*: *DataType*, ***kwargs*)

Bases: *NumericData*

classmethod **ndv**() → int

No-Data-Value

classmethod **primitive_type**() → *PrimitiveTypeEnum*

geoh5py.data.numeric_data

class geoh5py.data.numeric_data.**NumericData**(*data_type*: *DataType*, ***kwargs*)

Bases: *Data*, ABC

Data container for floats values

check_vector_length(*values*) → ndarray

Check for possible mismatch between the length of values stored and the expected number of cells or vertices.

classmethod **primitive_type**() → *PrimitiveTypeEnum*

property values: np.ndarray | None

Returns

values: An array of float values

geoh5py.data.primitive_type_enum

class geoh5py.data.primitive_type_enum.**PrimitiveTypeEnum**(*value*)

Bases: Enum

Known data type.

Available options:

BLOB = 6

DATETIME = 8

FILENAME = 5

FLOAT = 2

GEOMETRIC = 9

INTEGER = 1

INVALID = 0

REFERENCED = 4

TEXT = 3

VECTOR = 7

geoh5py.data.reference_value_map

class geoh5py.data.reference_value_map.**ReferenceValueMap**(color_map: dict[int, str] = None)

Bases: ABC

Maps from reference index to reference value of ReferencedData.

property map

dict: A reference dictionary mapping values to strings

geoh5py.data.referenced_data

class geoh5py.data.referenced_data.**ReferencedData**(data_type: DataType, **kwargs)

Bases: IntegerData

Reference data described by indices and associated strings.

classmethod primitive_type() → PrimitiveTypeEnum

property value_map

Pointer to the data.data_type.DataType.value_map

geoh5py.data.text_data

class geoh5py.data.text_data.**CommentsData**(data_type: DataType, **kwargs)

Bases: Data

Comments added to an Object or Group. Stored as a list of dictionaries with the following keys:

```
comments = [  
    {  
        "Author": "username",  
        "Date": "2020-05-21T10:12:15",  
        "Text": "A text comment."  
    },  
]
```

classmethod primitive_type() → PrimitiveTypeEnum

property values: list[dict] | None

list List of comments

class geoh5py.data.text_data.**TextData**(data_type: DataType, **kwargs)

Bases: Data

classmethod primitive_type() → PrimitiveTypeEnum

property values: np.ndarray | str | None

str Text value.

geoh5py.data.unknown_data

```
class geoh5py.data.unknown_data.UnknownData(data_type: DataType, association: DataAssociationEnum,
                                             name: str, uid: Optional[UUID] = None)
```

Bases: *Data*

```
classmethod primitive_type() → PrimitiveTypeEnum
```

2.3.2 geoh5py.groups

geoh5py.groups.container_group

```
class geoh5py.groups.container_group.ContainerGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for the basic Container group.

```
classmethod default_type_uid() → UUID
```

geoh5py.groups.custom_group

```
class geoh5py.groups.custom_group.CustomGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

A custom group, for an unlisted Group type.

```
classmethod default_type_uid() → uuid.UUID | None
```

geoh5py.groups.drillhole_group

```
class geoh5py.groups.drillhole_group.DrillholeGroup(group_type: GroupType, name='Drillholes
Group', **kwargs)
```

Bases: *Group*

The type for the group containing drillholes.

```
classmethod default_type_uid() → UUID
```

geoh5py.groups.giftools_group

```
class geoh5py.groups.giftools_group.GiftoolsGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a GIFtools group.

```
classmethod default_type_uid() → UUID
```

geoh5py.groups.group

class geoh5py.groups.group.**Group**(group_type: GroupType, **kwargs)

Bases: *Entity*

Base Group class

add_comment(comment: str, author: Optional[str] = None)

Add text comment to an object.

Parameters

- **comment** – Text to be added as comment.
- **author** – Author’s name or contributors.

property comments

Fetch a *CommentsData* entity from children.

abstract classmethod default_type_uid() → uuid.UUID | None

property entity_type: *GroupType*

classmethod find_or_create_type(workspace: workspace.Workspace, **kwargs) → *GroupType*

geoh5py.groups.group_type

class geoh5py.groups.group_type.**GroupType**(workspace: workspace.Workspace, **kwargs)

Bases: *EntityType*

property allow_delete_content: bool

bool: [True] Allow to delete the group *children*.

property allow_move_content: bool

bool: [True] Allow to move the group *children*.

static create_custom(workspace: workspace.Workspace, **kwargs) → *GroupType*

Creates a new instance of GroupType for an unlisted custom Group type with a new auto-generated UUID.

classmethod find_or_create(workspace: workspace.Workspace, entity_class, **kwargs) → *GroupType*

Find or creates an EntityType with given UUID that matches the given Group implementation class.

Parameters

- **workspace** – An active Workspace class
- **entity_class** – An Group implementation class.

Returns

A new instance of GroupType.

geoh5py.groups.notype_group

```
class geoh5py.groups.notype_group.NoTypeGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

A group with no type.

classmethod `default_type_uid()` → UUID

geoh5py.groups.property_group

```
class geoh5py.groups.property_group.PropertyGroup(**kwargs)
```

Bases: ABC

Property group listing data children of an object. This group is not registered to the workspace and only visible to the parent object.

property association: *DataAssociationEnum*

DataAssociationEnum Data association

property attribute_map: dict

dict Attribute names mapping between geoh5 and geoh5py

property name: str

str Name of the group

property parent: *Entity*

The parent *ObjectBase*

property properties: list[uuid.UUID]

List of unique identifiers for the *Data* contained in the property group.

property property_group_type: str

property uid: UUID

uuid.UUID Unique identifier

geoh5py.groups.root_group

```
class geoh5py.groups.root_group.RootGroup(group_type: GroupType, **kwargs)
```

Bases: *NoTypeGroup*

The Root group of a workspace.

property parent

Parental entity of root is always None

geoh5py.groups.simpeg_group

class geoh5py.groups.simpeg_group.SimPEGGroup(*group_type*: GroupType, ***kwargs*)

Bases: *Group*

Group for SimPEG inversions.

classmethod default_type_uid() → UUID

property options: dict | None

Metadata attached to the entity.

2.3.3 geoh5py.io

geoh5py.io.h5_reader

class geoh5py.io.h5_reader.H5Reader

Bases: object

Class to read information from a geoh5 file.

classmethod fetch_array_attribute(*file*: str | h5py.File, *uid*: uuid.UUID, *entity_type*: str, *key*: str) → np.ndarray | None

Get an entity attribute stores as array such as *cells*.

Parameters

- **file** – h5py.File or name of the target geoh5 file
- **uid** – Unique identifier of the target object.
- **entity_type** – Group type to fetch entity from.
- **key** – Field attribute name.

Return cells

numpy.ndarray of int.

classmethod fetch_attributes(*file*: str | h5py.File, *uid*: uuid.UUID, *entity_type*: str) → tuple[dict, dict, dict]

Get attributes of an *Entity*.

Parameters

- **file** – h5py.File or name of the target geoh5 file
- **uid** – Unique identifier
- **entity_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group_type’, ‘data_type’, ‘object_type’

Returns

attributes:

[obj:dict of attributes for the *Entity*]

type_attributes:

[obj:dict of attributes for the Entity type]

property_groups:

[obj:dict of data uuid.UUID]

classmethod `fetch_children`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *entity_type*: str) → dict

Get *children* of an *Entity*.

Parameters

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier
- **entity_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group_type’, ‘data_type’, ‘object_type’

Return children

[{*uuid*: type}, ...] List of dictionaries for the children *uid* and type

classmethod `fetch_concatenated_attributes`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *entity_type*: str, *label*: str) → list | dict | None

Get ‘Attributes’, ‘Data’ or ‘Index’ from Concatenator group.

Parameters

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier
- **entity_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group_type’, ‘data_type’, ‘object_type’
- **label** – Group identifier for the attribute requested.

Return children

[{*uuid*: type}, ...] List of dictionaries for the children *uid* and type

classmethod `fetch_concatenated_values`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *entity_type*: str, *label*: str) → tuple | None

Get *children* values of concatenated group.

Parameters

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier
- **entity_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group_type’, ‘data_type’, ‘object_type’
- **label** – Group identifier for the attribute requested.

Return children

[{*uuid*: type}, ...] List of dictionaries for the children *uid* and type

classmethod `fetch_file_object`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *file_name*: str) → bytes | None

Load data associated with an image file

Parameters

- **file** – Name of the target geoh5 file
- **uid** – Unique identifier of the target entity
- **file_name** – Name of the file stored as bytes data.

Return values

Data file stored as bytes

classmethod `fetch_metadata`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *entity_type*: str = 'Objects', *argument*: str = 'Metadata') → str | dict | None

Fetch text of dictionary type attributes of an entity.

Parameters

- **file** – Target h5 file.
- **uid** – Unique identifier of the target Entity.
- **entity_type** – Base type of the target Entity.
- **argument** – Label name of the dictionary.

classmethod `fetch_project_attributes`(*file*: str | *h5py.File*) → dict[Any, Any]

Get attributes of an *Entity*.

Parameters

file – *h5py.File* or name of the target geoh5 file

Return attributes

dict of attributes.

classmethod `fetch_property_groups`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*) → dict[str, dict[str, str]]

Get the property groups.

Parameters

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier of the target entity

Return property_group_attributes

dict of property groups and respective attributes.

```
property_group = {
    "group_1": {"attribute": value, ...},
    ...,
    "group_N": {"attribute": value, ...},
}
```

classmethod `fetch_type`(*file*: str | *h5py.File*, *uid*: *uuid.UUID*, *entity_type*: str) → dict

Fetch a type from the target geoh5.

Parameters

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier of the target entity
- **entity_type** – One of 'Data', 'Object' or 'Group'

Return property_group_attributes

dict of property groups and respective attributes.

classmethod `fetch_type_attributes`(*type_handle*: *Group*) → dict

Fetch type attributes from a given h5 handle.

classmethod `fetch_uuids`(*file*: str | *h5py.File*, *entity_type*: str) → list

Fetch all uuids of a given type from geoh5

Parameters

- **file** – *h5py.File* or name of the target geoh5 file

- **entity_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group_type’, ‘data_type’, ‘object_type’

Return uuids

[uuid1, uuid2, ...] List of uuids

classmethod **fetch_value_map**(*h5_handle: Group*) → dict

Get data value_map

Parameters

h5_handle – Handle to the target h5 group.

Return value_map

dict of {int: str}

classmethod **fetch_values**(*file: str | h5py.File, uid: uuid.UUID*) → np.ndarray | str | float | None

Get data *values*

Parameters

- **file** – h5py.File or name of the target geoh5 file
- **uid** – Unique identifier of the target entity

Return values

numpy.array of float

static **format_type_string**(*string: str*) → str

Format names used for types.

geoh5py.io.h5_writer

class geoh5py.io.h5_writer.**H5Writer**

Bases: object

Writing class to a geoh5 file.

classmethod **clear_stats_cache**(*file: str | h5py.File, entity: Data*) → None

Clear the StatsCache dataset.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.

classmethod **create_dataset**(*entity_handle, dataset: ndarray, label: str*) → None

Create a dataset on geoh5.

Parameters

- **entity_handle** – Pointer to a hdf5 group
- **dataset** – Array of values to be written
- **label** – Name of the dataset on file

classmethod **create_geoh5**(*file: str | h5py.File, workspace: workspace.Workspace*)

Add the geoh5 core structure.

Parameters

- **file** – Name or handle to a geoh5 file.

- **workspace** – *Workspace* object defining the project structure.

Return h5file

Pointer to a geoh5 file.

classmethod `fetch_handle(file: str | h5py.File, entity, return_parent: bool = False) → None | h5py.Group`

Get a pointer to an *Entity* in geoh5.

Parameters

- **file** – Name or handle to a geoh5 file
- **entity** – Target *Entity*
- **return_parent** – Option to return the handle to the parent entity.

Return entity_handle

HDF5 pointer to an existing entity, parent or None if not found.

static `remove_child(file: str | h5py.File, uid: uuid.UUID, ref_type: str, parent: Entity) → None`

Remove a child from a parent.

Parameters

- **file** – Name or handle to a geoh5 file
- **uid** – uuid of the target *Entity*
- **ref_type** – Input type from: ‘Types’, ‘Groups’, ‘Objects’ or ‘Data’
- **parent** – Remove entity from parent.

static `remove_entity(file: str | h5py.File, uid: uuid.UUID, ref_type: str, parent: Entity = None) → None`

Remove an entity and its type from the target geoh5 file.

Parameters

- **file** – Name or handle to a geoh5 file
- **uid** – uuid of the target *Entity*
- **ref_type** – Input type from: ‘Types’, ‘Groups’, ‘Objects’ or ‘Data’
- **parent** – Remove entity from parent.

classmethod `save_entity(file: str | h5py.File, entity, add_children: bool = True) → h5py.Group`

Write an *Entity* to geoh5 with its *children*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.
- **add_children** – Add *children*.

`str_type = dtype('0')`

classmethod `update_concatenated_field(file: str | h5py.File, entity, attribute: str, channel: str) → None`

Update the attributes of a concatenated *Entity*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.

- **attribute** – Name of the attribute to get updated.
- **channel** – Name of the data or index to be modified.

classmethod `update_field(file: str | h5py.File, entity, attribute: str, **kwargs) → None`

Update the attributes of an *Entity*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.
- **attribute** – Name of the attribute to get updated.

classmethod `write_array_attribute(file: str | h5py.File, entity, attribute, values=None, **kwargs) → None`

Add surveys of an object.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.
- **attribute** – Name of the attribute to be written to geoh5

classmethod `write_attributes(file: str | h5py.File, entity) → None`

Write attributes of an *Entity*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Entity with attributes to be added to the geoh5 file.

classmethod `write_color_map(file: str | h5py.File, entity_type: shared.EntityType) → None`

Add *ColorMap* to a *DataType*.

Parameters

- **file** – Name or handle to a geoh5 file
- **entity_type** – Target entity_type with color_map

classmethod `write_data_values(file: str | h5py.File, entity, attribute, values=None) → None`

Add data *values*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.
- **attribute** – Name of the attribute to be written to geoh5

classmethod `write_entity(file: str | h5py.File, entity) → h5py.Group`

Add an *Entity* and its attributes to geoh5. The function returns a pointer to the entity if already present on file.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.

Return entity

Pointer to the written entity. Active link if “close_file” is False.

classmethod write_entity_type(file: str | h5py.File, entity_type: shared.EntityType) → h5py.Group

Add an *EntityType* to geoh5.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity_type** – Entity with type to be added.

Return type

Pointer to *EntityType* in geoh5.

classmethod write_file_name_data(entity_handle: Group, entity: FilenameData, values: bytes) → None

Write a dataset for the file name and file blob.

Parameters

- **entity_handle** – Pointer to the geoh5 Group.
- **entity** – Target *FilenameData* entity.
- **values** – Bytes data

classmethod write_properties(file: str | h5py.File, entity: Entity) → None

Add properties of an *Entity*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.

classmethod write_property_groups(file: str | h5py.File, entity) → None

Write *PropertyGroup* associated with an *Entity*.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target *Entity*.

classmethod write_to_parent(file: str | h5py.File, entity: Entity, recursively=False) → None

Add/create an *Entity* and add it to its parent.

Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Entity to be added or linked to a parent in geoh5.
- **recursively** – Add parents recursively until reaching the *RootGroup*.

classmethod write_value_map(file: str | h5py.File, entity_type: shared.EntityType) → None

Add *ReferenceValueMap* to a *DataType*.

Parameters

- **file** – Name or handle to a geoh5 file
- **entity_type** – Target entity_type with value_map

classmethod `write_visible(file: str | h5py.File, entity) → None`

Needs revision once Visualization is implemented

Parameters

- **file** – Name or handle to a geoh5 file
- **entity** – Target entity

2.3.4 geoh5py.objects

`geoh5py.objects.surveys`

`geoh5py.objects.surveys.electromagnetics`

`geoh5py.objects.surveys.electromagnetics.airborne_tem`

class `geoh5py.objects.surveys.electromagnetics.airborne_tem.AirborneTEMReceivers`(*object_type*: Object-
Type,
***kwargs*)

Bases: *BaseAirborneTEM*

Airborne time-domain electromagnetic receivers class.

property `default_transmitter_type`

Returns

Transmitter class

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

property `type`

Survey element type

class `geoh5py.objects.surveys.electromagnetics.airborne_tem.AirborneTEMTransmitters`(*object_type*: Ob-
ject-
Type,
***kwargs*)

Bases: *BaseAirborneTEM*

Airborne time-domain electromagnetic transmitters class.

property `default_receiver_type`

Returns

Transmitter class

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

property type

Survey element type

class geoh5py.objects.surveys.electromagnetics.airborne_tem.**BaseAirborneTEM**(*object_type:* ObjectType, ***kwargs*)

Bases: *BaseEMSurvey, Curve*

property crossline_offset: float | uuid.UUID | None

Numeric value or property UUID for the crossline offset between receiver and transmitter.

property default_input_types: list[str]

Input types. Must be one of 'Rx', 'Tx', 'Tx and Rx'.

property default_metadata: dict

Default dictionary of metadata for AirborneTEM entities.

property default_units: list[str]

Accepted time units. Must be one of "Seconds (s)", "Milliseconds (ms)", "Microseconds (us)" or "Nanoseconds (ns)"

fetch_metadata(*key: str*) → float | uuid.UUID | None

Fetch entry from the metadata.

property inline_offset: float | uuid.UUID | None

Numeric value or property UUID for the inline offset between receiver and transmitter.

property loop_radius: float | None

Transmitter loop radius

property pitch: float | uuid.UUID | None

Numeric value or property UUID for the pitch angle of the transmitter loop.

property relative_to_bearing: bool | None

Data relative_to_bearing

property roll: float | uuid.UUID | None

Numeric value or property UUID for the roll angle of the transmitter loop.

set_metadata(*key: str, value: float | uuid.UUID | None*)

property timing_mark: float | None

Timing mark from the beginning of the discrete *waveform*. Generally used as the reference (time=0.0) for the provided (-) on-time an (+) off-time channels.

property vertical_offset: float | uuid.UUID | None

Numeric value or property UUID for the vertical offset between receiver and transmitter.

property waveform: np.ndarray | None

Discrete waveform of the TEM source provided as `numpy.array` of type `float`, shape(n, 2)

```

waveform = [
    [time_1, current_1],
    [time_2, current_2],
    ...
]
    
```

property yaw: float | uuid.UUID | None

Numeric value or property UUID for the yaw angle of the transmitter loop.

geoh5py.objects.surveys.electromagnetics.base

class geoh5py.objects.surveys.electromagnetics.base.**BaseEMSurvey**(*object_type*: *ObjectType*,
***kwards*)

Bases: *ObjectBase*

A base electromagnetics survey object.

add_components_data(*data*: *dict*) → list[*PropertyGroup*]

Add lists of data components to an EM survey. The name of each component is appended to the metadata 'Property groups'.

Data channels must be provided for every frequency or time in order specified by `channels`. The data channels can be supplied as either a list of `geoh5py.data.float_data.FloatData` entities or `uuid.UUID`

```
data = {
    "Component A": [
        data_entity_1,
        data_entity_2,
    ],
    "Component B": [...],
}
```

or a nested dictionary of arguments defining new Data entities as defined by the `add_data()` method.

```
data = {
    "Component A": {
        time_1: {
            'values': [v_11, v_12, ...],
            "entity_type": entity_type_A,
            ...,
        },
        time_2: {...},
        ...,
    },
    "Component B": {...},
}
```

Parameters

data – Dictionary of data components to be added to the survey.

Returns

List of property groups for all components added.

add_validate_component_data(*name*: *str*, *data_block*: list | *dict*)

Append a property group to the entity and its metadata after validations.

property channels

List of measured channels.

property components: dict | None

Rapid access to the list of data entities for all components.

copy(*parent=None, copy_children: bool = True*) → *BaseEMSurvey*

Function to copy a AirborneTEMReceivers to a different parent entity.

Parameters

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy_children** – Create copies of AirborneTEMReceivers along with it.

Return entity

Registered AirborneTEMReceivers to the workspace.

property default_input_types: list[str] | None

Input types. Must be one of 'Rx', 'Tx', 'Tx and Rx'.

property default_metadata

Default metadata structure. Implemented on the child class.

property default_receiver_type: type

Returns

Receivers implemented on the child class.

property default_transmitter_type: type

Returns

Transmitters implemented on the child class.

classmethod default_type_uid() → UUID

Default unique identifier. Implemented on the child class.

property default_units: list[str] | None

Accepted sampling units.

edit_metadata(*entries: dict[str, Any]*)

Utility function to edit or add metadata fields and trigger an update on the receiver and transmitter entities.

Parameters

entries – Metadata key value pairs.

property input_type: str | None

Data input type. Must be one of 'Rx', 'Tx' or 'Tx and Rx'

property metadata

Metadata attached to the entity.

property receivers: BaseEMSurvey | None

The associated TEM receivers.

property survey_type: str | None

Data input type. Must be one of 'Rx', 'Tx' or 'Tx and Rx'

property transmitters: BaseEMSurvey | None

The associated TEM transmitters (sources).

property type

Survey element type

property unit: float | None

Default channel units for time or frequency defined on the child class.

geoh5py.objects.surveys.electromagnetics.magnetotellurics

```
class geoh5py.objects.surveys.electromagnetics.magnetotellurics.MTReceivers(object_type:
    ObjectType,
    **kwargs)
```

Bases: *BaseEMSurvey*, *Points*

A magnetotellurics survey object.

property default_input_types: list[str]

Input types. Must be 'Rx only'

property default_metadata: dict

Returns

Default unique identifier

classmethod default_type_uid() → UUID

Returns

Default unique identifier

property default_units: list[str]

Accepted time units. Must be one of "Seconds (s)", "Milliseconds (ms)", "Microseconds (us)" or "Nanoseconds (ns)"

property type

Survey element type

geoh5py.objects.surveys.electromagnetics.tipper

```
class geoh5py.objects.surveys.electromagnetics.tipper.BaseTipper(object_type: ObjectType,
    base_stations:
    TipperBaseStations | None =
    None, **kwargs)
```

Bases: *BaseEMSurvey*

Base tipper survey class.

property base_stations: TipperBaseStations | None

The base station entity

property default_input_types: list[str]

Input types. Must be 'Rx and base stations'

property default_metadata: dict

Returns

Default unique identifier

property default_units: list[str]

Accepted time units. Must be one of "Seconds (s)", "Milliseconds (ms)", "Microseconds (us)" or "Nanoseconds (ns)"

```
class geoh5py.objects.surveys.electromagnetics.tipper.TipperBaseStations(object_type:
    ObjectType,
    **kwargs)
```

Bases: *BaseTipper*, *Points*

A z-tipper EM survey object.

property default_receiver_type

Returns

Receiver class

classmethod default_type_uid() → UUID

Returns

Default unique identifier

property type

Survey element type

class geoh5py.objects.surveys.electromagnetics.tipper.**TipperReceivers**(*object_type*: *ObjectType*,
***kwargs*)

Bases: *BaseTipper*, *Curve*

A z-tipper EM survey object.

classmethod default_type_uid() → UUID

Returns

Default unique identifier

property type

Survey element type

geoh5py.objects.surveys.direct_current

class geoh5py.objects.surveys.direct_current.**CurrentElectrode**(*object_type*: *ObjectType*,
***kwargs*)

Bases: *PotentialElectrode*

Ground direct current electrode (transmitter).

add_default_ab_cell_id()

Utility function to set ab_cell_id's based on curve cells.

copy(*parent*=None, *copy_children*: bool = True)

Function to copy a survey to a different parent entity.

Parameters

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy_children** – Create copies of all children entities along with it.

Return entity

Registered Entity to the workspace.

property current_electrodes

The associated current electrode object (sources).

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

property `potential_electrodes`: *PotentialElectrode* | None

The associated potential_electrodes (receivers)

class `geoh5py.objects.surveys.direct_current.PotentialElectrode`(*object_type*: *ObjectType*,
***kwargs*)

Bases: *Curve*

Ground potential electrode (receiver).

property `ab_cell_id`: *ReferencedData* | None

Reference data entity mapping cells to a unique current dipole.

property `ab_map`: *dict* | None

Get the *ReferencedData.value_map* of the `ab_value_id`

copy(*parent*=None, *copy_children*: *bool* = True)

Function to copy a survey to a different parent entity.

Parameters

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy_children** – Create copies of all children entities along with it.

Return entity

Registered Entity to the workspace.

property `current_electrodes`

The associated current electrode object (sources).

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

property `metadata`

Metadata attached to the entity.

property `potential_electrodes`

The associated potential_electrodes (receivers)

geoh5py.objects.surveys.magnetics

class `geoh5py.objects.surveys.magnetics.AirborneMagnetics`(*object_type*: *ObjectType*, ***kwargs*)

Bases: *Curve*

An airborne magnetic survey object.

Warning: Partially implemented.
--

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

geoh5py.objects.block_model

class `geoh5py.objects.block_model.BlockModel`(*object_type*: `ObjectType`, ***kwargs*)

Bases: `ObjectBase`

Rectilinear 3D tensor mesh defined by three perpendicular axes. Each axis is divided into discrete intervals that define the cell dimensions. Nodal coordinates are determined relative to the origin and the sign of cell delimiters. Negative and positive cell delimiters are accepted to denote relative offsets from the origin.

property `cell_delimiters`

property `centroids`

`numpy.array`, shape (*n_cells*, 3): Cell center locations in world coordinates.

```
centroids = [
    [x_1, y_1, z_1],
    ...,
    [x_N, y_N, z_N]
]
```

classmethod `default_type_uid()` → UUID

Returns

Default unique identifier

property `n_cells`: `int` | `None`

`int`: Total number of cells

property `origin`: `ndarray`

`numpy.array` of `float`, shape (3,): Coordinates of the origin.

property `rotation`: `float`

`float`: Clockwise rotation angle (degree) about the vertical axis.

property `shape`: `tuple` | `None`

list of `int`, len (3,): Number of cells along the u, v and z-axis

property `u_cell_delimiters`: `np.ndarray` | `None`

`numpy.array` of `float`: Nodal offsets along the u-axis relative to the origin.

property `u_cells`: `np.ndarray` | `None`

`numpy.array` of `float`, shape (*shape* [0],): Cell size along the u-axis.

property `v_cell_delimiters`: `np.ndarray` | `None`

`numpy.array` of `float`: Nodal offsets along the v-axis relative to the origin.

property `v_cells`: `np.ndarray` | `None`

`numpy.array` of `float`, shape (*shape* [1],): Cell size along the v-axis.

property `z_cell_delimiters`: `np.ndarray` | `None`

`numpy.array` of `float`: Nodal offsets along the z-axis relative to the origin (positive up).

property z_cells: np.ndarray | None

numpy.array of float, shape (*shape* [2],): Cell size along the z-axis

geoh5py.objects.curve

class geoh5py.objects.curve.**Curve**(*object_type: ObjectType, **kwargs*)

Bases: *Points*

Curve object defined by a series of line segments (*cells*) connecting *vertices*.

property cells: np.ndarray | None

numpy.ndarray of int, shape (*, 2): Array of indices defining segments connecting vertices. Defined based on *parts* if set by the user.

property current_line_id

classmethod default_type_uid() → UUID

Returns

Default unique identifier

property parts

numpy.array of int, shape (*n_vertices*, 2): Group identifiers for vertices connected by line segments as defined by the *cells* property. The definition of the *cells* property get modified by the setting of parts.

property unique_parts

list of int: Unique *parts* identifiers.

geoh5py.objects.drillhole

class geoh5py.objects.drillhole.**Drillhole**(*object_type: ObjectType, **kwargs*)

Bases: *Points*

Drillhole object class defined by

Warning: Not yet implemented.

add_data(*data: dict, property_group: str = None*) → *Data* | list[*Data*]

Create *Data* specific to the drillhole object from dictionary of name and arguments. A keyword ‘depth’ or ‘from-to’ with corresponding depth values is expected in order to locate the data along the well path.

Parameters

data – Dictionary of data to be added to the object, e.g.

```
data_dict = {
    "data_A": {
        'values', [v_1, v_2, ...],
        "from-to": numpy.ndarray,
    },
    "data_B": {
        'values', [v_1, v_2, ...],
        "depth": numpy.ndarray,
    },
}
```

Returns

List of new Data objects.

add_vertices(*xyz*)

Function to add vertices to the drillhole

property cells: **np.ndarray** | **None**

numpy.ndarray of int, shape (*, 2): Array of indices defining segments connecting vertices.

property collar

numpy.array of float, shape (3,): Coordinates of the collar

property cost

float: Cost estimate of the drillhole

property default_collocation_distance

Minimum collocation distance for matching depth on merge

classmethod default_type_uid() → UUID

property depths: *FloatData* | **None**

desurvey(*depths*)

Function to return x, y, z coordinates from depth.

property end_of_hole: **float** | **None**

End of drillhole in meters

property locations: **np.ndarray** | **None**

Lookup array of the well path in x, y, z coordinates.

property planning: **str**

Status of the hole on of “Default”, “Ongoing”, “Planned”, “Completed” or “No status”

sort_depths()

Read the ‘DEPTH’ data and sort all Data.values if needed

property surveys: **np.ndarray** | **None**

Coordinates of the surveys

property trace: **np.ndarray** | **None**

numpy.array: Drillhole trace defining the path in 3D

property trace_depth: **np.ndarray** | **None**

numpy.array: Drillhole trace depth from top to bottom

validate_data(*attributes: dict, property_group=None*) → tuple

Validate input drillhole data attributes.

Parameters

- **attributes** – Dictionary of data attributes.
- **property_group** – Input property group to validate against.

validate_depth_data(*from_to, values, collocation_distance=0.0001*) → str

Compare new and current depth values and re-use the property group if possible. Otherwise a new property group is added.

Parameters

- **from_to** – Array of from-to values.
- **values** – Data values to be added on the from-to intervals.

Collocation_distance

Threshold on the comparison between existing depth values.

validate_interval_data(*from_to*: *np.ndarray* | *list*, *values*: *np.ndarray*, *collocation_distance*: *float* = 0.0001)

Compare new and current depth values, append new vertices if necessary and return an augmented values vector that matches the vertices indexing.

validate_log_data(*depth*: *ndarray*, *input_values*: *ndarray*, *collocation_distance*=0.0001) → *ndarray*

Compare new and current depth values. Append new vertices if necessary and return an augmented values vector that matches the vertices indexing.

`geoh5py.objects.drillhole.compute_deviation`(*surveys*: *np.ndarray*, *axis*: *str*) → *np.ndarray* | *None*

Compute deviation from survey parameters

geoh5py.objects.geo_image

class `geoh5py.objects.geo_image.GeoImage`(*object_type*: *ObjectType*, ***kwargs*)

Bases: *ObjectBase*

Image object class.

Warning: Not yet implemented.

property cells: *np.ndarray* | *None*

numpy.ndarray of *int*, shape (*, 2): Array of indices defining segments connecting vertices. Defined based on *parts* if set by the user.

classmethod default_type_uid() → *UUID*

property default_vertices

Assign the default vertices based on image pixel count

georeference(*reference*: *np.ndarray* | *list*, *locations*: *np.ndarray* | *list*)

Georeference the image vertices (corners) based on input reference and corresponding world coordinates.

Parameters

- **reference** – Array of integers representing the reference used as reference points.
- **locations** – Array of floats for the corresponding world coordinates for each input pixel.

Return vertices

Corners (vertices) in world coordinates.

property image

Get the image as a *PIL*.Image object.

property image_data

Get the *FilenameData* entity holding the image.

property vertices: *np.ndarray* | *None*

vertices: Defines the four corners of the *geo_image*

geoh5py.objects.grid2d**class** geoh5py.objects.grid2d.**Grid2D**(*object_type*: *ObjectType*, ***kwargs*)Bases: *ObjectBase*

Rectilinear 2D grid of uniform cell size. The grid can be oriented in 3D space through horizontal *rotation* and *dip* parameters. Nodal coordinates are determined relative to the origin and the sign of cell delimiters.

property cell_center_u: np.ndarray | Nonenumpy.array of float, shape(*u_count*,): Cell center local coordinate along the u-axis.**property cell_center_v: np.ndarray | None**numpy.array of float shape(*u_count*,): The cell center local coordinate along the v-axis.**property centroids: np.ndarray | None**numpy.array of float, shape (*n_cells*, 3): Cell center locations in world coordinates.

```
centroids = [  
    [x_1, y_1, z_1],  
    ...,  
    [x_N, y_N, z_N]  
]
```

classmethod default_type_uid() → UUID**Returns**

Default unique identifier

property dip: float

float: Dip angle from horizontal (positive down) in degrees.

property n_cells: int | None

int: Total number of cells.

property origin: ndarray

numpy.array of float, shape (3,): Coordinates of the origin.

property rotation: float

float: Clockwise rotation angle (degree) about the vertical axis.

property shape: tuple | None

list of int, len (2,): Number of cells along the u and v-axis.

property u_cell_size: float | None

float: Cell size along the u-axis.

property u_count: int | None

int: Number of cells along u-axis

property v_cell_size: float | None

float: Cell size along the v-axis

property v_count: int | None

int: Number of cells along v-axis

property vertical: bool | None

bool: Set the grid to be vertical.

geoh5py.objects.label

class geoh5py.objects.label.**Label**(*object_type*: ObjectType, ***kwargs*)

Bases: *ObjectBase*

Label object for annotation in viewport.

Warning: Not yet implemented.

classmethod **default_type_uid**() → UUID

geoh5py.objects.notype_object

class geoh5py.objects.notype_object.**NoTypeObject**(*object_type*: ObjectType, ***kwargs*)

Bases: *ObjectBase*

Generic Data object without a registered type

classmethod **default_type_uid**() → UUID

geoh5py.objects.object_base

class geoh5py.objects.object_base.**ObjectBase**(*object_type*: ObjectType, ***kwargs*)

Bases: *Entity*

Object base class.

add_comment(*comment*: str, *author*: Optional[str] = None)

Add text comment to an object.

Parameters

- **comment** – Text to be added as comment.
- **author** – Name of author or defaults to *contributors*.

add_data(*data*: dict, *property_group*: str = None) → *Data* | list[*Data*]

Create *Data* from dictionary of name and arguments. The provided arguments can be any property of the target *Data* class.

Parameters

data – Dictionary of data to be added to the object, e.g.

```
data = {
    "data_A": {
        'values': [v_1, v_2, ...],
        'association': 'VERTEX'
    },
    "data_B": {
        'values': [v_1, v_2, ...],
        'association': 'CELLS'
    },
}
```

Returns

List of new Data objects.

add_data_to_group(*data: list | Data | uuid.UUID, name: str*) → *PropertyGroup*

Append data children to a *PropertyGroup*. All given data must be children of the parent object.

Parameters

- **data** – *Data* object, *uid* or *name* of data.
- **name** – Name of a *PropertyGroup*. A new group is created if none exist with the given name.

Returns

The target property group.

property cells

`numpy.array of int`: Array of indices defining the connection between *vertices*.

property comments

Fetch a *CommentsData* entity from children.

abstract classmethod default_type_uid() → UUID

property entity_type: *ObjectType*

EntityType: Object type.

property faces

find_or_create_property_group(***kwargs*) → *PropertyGroup*

Find or create *PropertyGroup* from given name and properties.

Parameters

kwargs – Any arguments taken by the *PropertyGroup* class.

Returns

A new or existing *PropertyGroup*

classmethod find_or_create_type(*workspace: workspace.Workspace, **kwargs*) → *ObjectType*

Find or create a type instance for a given object class.

Parameters

workspace – Target *Workspace*.

Returns

The *ObjectType* instance for the given object class.

get_data(*name: str*) → list[*Data*]

Get a child *Data* by name.

Parameters

name – Name of the target child data

Returns

A list of children Data objects

get_data_list() → list[str]

Get a list of names of all children *Data*.

Returns

List of names of data associated with the object.

property last_focus: str

bool: Object visible in camera on start.

property n_cells: int | None

int: Number of cells.

property n_vertices: int | None

int: Number of vertices.

property property_groups: list[PropertyGroup] | None

list of *PropertyGroup*.

validate_data_association(attribute_dict)

Get a dictionary of attributes and validate the data 'association' keyword.

static validate_data_type(attribute_dict)

Get a dictionary of attributes and validate the type of data.

property vertices

numpy.array of float, shape (*, 3): Array of x, y, z coordinates defining the position of points in 3D space.

geoh5py.objects.object_type

class geoh5py.objects.object_type.**ObjectType**(workspace: workspace.Workspace, **kwargs)

Bases: *EntityType*

Object type class

static create_custom(workspace: workspace.Workspace) → *ObjectType*

Creates a new instance of *ObjectType* for an unlisted custom Object type with a new auto-generated UUID.

Parameters

workspace – An active Workspace class

classmethod find_or_create(workspace: workspace.Workspace, entity_class, **kwargs) → *ObjectType*

Find or creates an *EntityType* with given `uuid.UUID` that matches the given Group implementation class.

It is expected to have a single instance of *EntityType* in the Workspace for each concrete Entity class.

Parameters

- **workspace** – An active Workspace class
- **entity_class** – An Group implementation class.

Returns

A new instance of *GroupType*.

geoh5py.objects.octree

class geoh5py.objects.octree.Octree(*object_type*: ObjectType, ***kwargs*)

Bases: *ObjectBase*

Octree mesh class that uses a tree structure such that cells can be subdivided it into eight octants.

base_refine()

Refine the mesh to its base octree level resulting in a single cell along the shortest dimension.

property centroids

numpy.array of float, shape (*n_cells*, 3): Cell center locations in world coordinates.

```
centroids = [  
    [x_1, y_1, z_1],  
    ...,  
    [x_N, y_N, z_N]  
]
```

classmethod default_type_uid() → UUID

property n_cells: int | None

int: Total number of cells in the mesh

property octree_cells: np.ndarray | None

numpy.ndarray of int, shape (*n_cells*, 4): Array defining the i, j, k position and size of each cell. The size defines the width of a cell in number of base cells.

```
cells = [  
    [i_1, j_1, k_1, size_1],  
    ...,  
    [i_N, j_N, k_N, size_N]  
]
```

property origin

numpy.array of float, shape (3,): Coordinates of the origin

property rotation: float

float: Clockwise rotation angle (degree) about the vertical axis.

property shape: tuple | None

list of int, len (3,): Number of cells along the u, v and w-axis.

property u_cell_size: float | None

float: Base cell size along the u-axis.

property u_count: int | None

int: Number of cells along u-axis.

property v_cell_size: float | None

float: Base cell size along the v-axis.

property v_count: int | None

int: Number of cells along v-axis.

property w_cell_size: float | None

float: Base cell size along the w-axis.

property w_count: int | None
 int: Number of cells along w-axis.

geoh5py.objects.points

class geoh5py.objects.points.**Points**(*object_type: ObjectType, **kwargs*)
 Bases: *ObjectBase*
 Points object made up of vertices.
classmethod **default_type_uid()** → UUID
property **vertices: np.ndarray | None**
vertices

geoh5py.objects.surface

class geoh5py.objects.surface.**Surface**(*object_type: ObjectType, **kwargs*)
 Bases: *Points*
 Surface object defined by vertices and cells
property **cells: np.ndarray | None**
 Array of vertices index forming triangles :return cells: numpy.array of int, shape (“*”, 3)
classmethod **default_type_uid()** → UUID

2.3.5 geoh5py.shared

geoh5py.shared.concatenation

class geoh5py.shared.concatenation.**Concatenated**(*entity_type, **kwargs*)
 Bases: *Entity*
 Class modifier for concatenated objects and data.
property **concatenator: Concatenator**
 Parental Concatenator entity.
get_data(*name: str*) → list[*Data*]
 Generic function to get data values from object.
get_data_list()
 Get list of data names.
property **parent: Concatenated | Concatenator**
property **property_groups: list | None**

class geoh5py.shared.concatenation.**Concatenator**(*group_type: GroupType, **kwargs*)
 Bases: *Group*
 Class modifier for concatenation of objects and data.

add_attribute(*uid: str*) → None

Add new element to the concatenated attributes.

Parameters

uid – Unique identifier of the new concatenated entity in str format.

add_save_concatenated(*child*) → None

Add or save a concatenated entity.

Parameters

child – Concatenated entity

property attributes_keys: list | None

List of uuids present in the concatenated attributes.

property concatenated_attributes: dict | None

Dictionary of concatenated objects and data attributes.

property concatenated_object_ids: list[bytes] | None

Dictionary of concatenated objects and data concatenated_object_ids.

property data: dict

Concatenated data values stored as a dictionary.

delete_index_data(*label: str, index: int*) → None

fetch_concatenated_objects() → dict

Load all concatenated children.

fetch_index(*entity: Concatenated, field: str*) → int | None

Fetch the array index for specific concatenated object and data field.

Parameters

- **entity** – Parent entity with data
- **field** – Name of the target data.

fetch_start_index(*entity: Concatenated, label: str*) → int

Fetch starting index for a given entity and label. Existing data is removed such that new entries can be appended.

Parameters

- **entity** – Concatenated entity to be added.
- **label** – Name of the attribute requiring an update.

fetch_values(*entity: Concatenated, field: str*) → np.ndarray | None

Get an array of values from concatenated data.

Parameters

- **entity** – Parent entity with data
- **field** – Name of the target data.

get_attributes(*uid: bytes | str | uuid.UUID*) → dict

Fast reference index to concatenated attribute keys.

property index: dict

Concatenated index stored as a dictionary.

property property_group_ids: list | None

Dictionary of concatenated objects and data property_group_ids.

update_array_attribute(entity: [Concatenated](#), field: str) → None

Update values stored as data. Row data and indices are first remove then appended.

Parameters

- **entity** – Concatenated entity with array values.
- **field** – Name of the valued field.

update_attributes(entity: [Concatenated](#), label: str) → None

Update a concatenated entity.

update_concatenated_attributes(entity: [Concatenated](#)) → None

Update the concatenated attributes. :param entity: Concatenated entity with attributes.

geoh5py.shared.entity

class geoh5py.shared.entity.**Entity**(uid: [uuid.UUID](#) | None = None, **kwargs)

Bases: ABC

Base Entity class

add_children(children: list[[shared.Entity](#)])

Parameters

children – Add a list of entities as [children](#)

add_file(file: str)

Add a file to the object or group stored as bytes on a [FilenameData](#)

Parameters

file – File name with path to import.

property allow_delete: bool

bool Entity can be deleted from the workspace.

property allow_move: bool

bool Entity can change [parent](#)

property allow_rename: bool

bool Entity can change name

property attribute_map: dict

dict Correspondence map between property names used in geoh5py and geoh5.

property children

list Children entities in the workspace tree

property clipping_ids: list[[uuid.UUID](#)] | None

List of clipping uuids

copy(parent=None, copy_children: bool = True)

Function to copy an entity to a different parent entity.

Parameters

- **parent** – Target parent to copy the entity under. Copied to current [parent](#) if None.

- **copy_children** – Create copies of all children entities along with it.

Return entity

Registered Entity to the workspace.

classmethod create(*workspace*, ***kwargs*)

Function to create an entity.

Parameters

- **workspace** – Workspace to be added to.
- **kwargs** – List of keyword arguments defining the properties of a class.

Return entity

Registered Entity to the workspace.

abstract property entity_type: shared.EntityType

classmethod fix_up_name(*name: str*) → str

If the given name is not a valid one, transforms it to make it valid :return: a valid name built from the given name. It simply returns the given name if it was already valid.

get_entity(*name: str | uuid.UUID*) → list[*Entity*]

Get a child *Data* by name.

Parameters

- **name** – Name of the target child data
- **entity_type** – Sub-select entities based on type.

Returns

A list of children *Data* objects

get_entity_list(*entity_type=<class 'abc.ABC'>*) → list[str]

Get a list of names of all children *Data*.

Parameters

entity_type – Option to sub-select based on type.

Returns

List of names of data associated with the object.

property metadata: dict | None

Metadata attached to the entity.

property name: str

str Name of the entity

property on_file: bool

Whether this Entity is already stored on *h5file*.

property parent

property partially_hidden: bool

Whether this Entity is partially hidden.

property public: bool

Whether this Entity is accessible in the workspace tree and other parts of the the user interface in ANALYST.

reference_to_uid(*value*: *Entity* | *str* | *uuid.UUID*) → list[*uuid.UUID*]

General entity reference translation.

Parameters

value – Either an *Entity*, string or uuid

Returns

List of unique identifier associated with the input reference.

remove_children(*children*: list[*shared.Entity*])

Remove children from the list of children entities.

Parameters

children – List of entities

Warning: Removing a child entity without re-assigning it to a different parent may cause it to become inactive. Inactive entities are removed from the workspace by `remove_none_referents()`.

remove_data_from_group(*data*: list | *Entity* | *uuid.UUID* | *str*, *name*: *str* = *None*) → *None*

Remove data children to a *PropertyGroup* All given data must be children of the parent object.

Parameters

- **data** – *Data* object, *uid* or *name* of data.
- **name** – Name of a *PropertyGroup*. A new group is created if none exist with the given name.

save(*add_children*: *bool* = *True*)

Alias method of `save_entity()`.

Parameters

add_children – Option to also save the children.

property uid: *UUID*

property visible: *bool*

Whether the Entity is visible in camera (checked in ANALYST object tree).

property workspace: *Workspace*

Workspace to which the Entity belongs to.

geoh5py.shared.entity_type

class geoh5py.shared.entity_type.**EntityType**(*workspace*: *ws.Workspace*, *uid*: *uuid.UUID* | *None* = *None*, ****kwargs**)

Bases: *ABC*

property attribute_map

dict Correspondence map between property names used in geoh5py and geoh5.

property description: *str* | *None*

classmethod **find**(*workspace*: *ws.Workspace*, *type_uid*: *uuid.UUID*) → *TEntityType* | *None*

Finds in the given *Workspace* the *EntityType* with the given *UUID* for this specific *EntityType* implementation class.

Returns

EntityType of None

property name: str | None

property on_file: bool

bool Entity already present in *h5file*.

property uid: UUID

uuid.UUID The unique identifier of an entity, either as stored in geoh5 or generated in uuid4() format.

property workspace: ws.Workspace

Workspace registering this type.

geoh5py.shared.exceptions

exception geoh5py.shared.exceptions.**AssociationValidationError**(*name: str, value: Entity | PropertyGroup | UUID, validation: Entity | Workspace*)

Bases: *BaseValidationError*

Error on association between child and parent entity validation.

static message(*name, value, validation*)

Builds custom error message.

exception geoh5py.shared.exceptions.**AtLeastOneValidationError**(*name: str, value: list[str]*)

Bases: *BaseValidationError*

static message(*name, value, validation=None*)

Builds custom error message.

exception geoh5py.shared.exceptions.**BaseValidationError**

Bases: ABC, Exception

Base class for custom exceptions.

abstract static message(*name, value, validation*)

Builds custom error message.

exception geoh5py.shared.exceptions.**Geoh5FileClosedError**

Bases: ABC, Exception

Error for closed geoh5 file.

exception geoh5py.shared.exceptions.**JSONParameterValidationError**(*name: str, err: str*)

Bases: Exception

Error on uuid validation.

static message(*name, err*)

exception geoh5py.shared.exceptions.**OptionalValidationError**(*name: str, value: Any | None, validation: bool*)

Bases: *BaseValidationError*

Error if None value provided to non-optional parameter.

static message(*name, value, validation*)

Builds custom error message.

exception `geoh5py.shared.exceptions.PropertyGroupValidationError`(*name: str, value: PropertyGroup, validation: str*)

Bases: `BaseValidationError`

Error on property group validation.

static message(*name, value, validation*)

Builds custom error message.

exception `geoh5py.shared.exceptions.RequiredValidationError`(*name: str*)

Bases: `BaseValidationError`

static message(*name, value=None, validation=None*)

Builds custom error message.

exception `geoh5py.shared.exceptions.ShapeValidationError`(*name: str, value: tuple[int], validation: tuple[int] | str*)

Bases: `BaseValidationError`

Error on shape validation.

static message(*name, value, validation*)

Builds custom error message.

exception `geoh5py.shared.exceptions.TypeValidationError`(*name: str, value: str, validation: str | list[str]*)

Bases: `BaseValidationError`

Error on type validation.

static message(*name, value, validation*)

Builds custom error message.

exception `geoh5py.shared.exceptions.UUIDValidationError`(*name: str, value: str*)

Bases: `BaseValidationError`

Error on uuid string validation.

static message(*name, value, validation=None*)

Builds custom error message.

exception `geoh5py.shared.exceptions.ValueValidationError`(*name: str, value: Any, validation: list[Any]*)

Bases: `BaseValidationError`

Error on value validation.

static message(*name, value, validation*)

Builds custom error message.

geoh5py.shared.utils

`geoh5py.shared.utils.as_str_if_utf8_bytes(value) → str`

Convert bytes to string

`geoh5py.shared.utils.as_str_if_uuid(value: UUID | Any) → str | Any`

Convert UUID to string used in geoh5.

`geoh5py.shared.utils.bool_value(value: int8) → bool`

Convert logical int8 to bool.

`geoh5py.shared.utils.compare_entities(object_a, object_b, ignore: list | None = None, decimal: int = 6) → None`

`geoh5py.shared.utils.dict_mapper(val, string_funcs: list[Callable], *args, omit: dict | None = None) → dict`

Recursion through nested dictionaries and applies mapping functions to values.

Parameters

- **val** – Value (could be another dictionary) to apply transform functions.
- **string_funcs** – Functions to apply on values within the input dictionary.
- **omit** – Dictionary of functions to omit.

Return val

Transformed values

`geoh5py.shared.utils.entity2uuid(value: Any) → UUID | Any`

Convert an entity to its UUID.

`geoh5py.shared.utils.fetch_h5_handle(file: str | h5py.File | Path, mode: str = 'r') → h5py.File`

Open in read+ mode a geoh5 file from string. If receiving a file instead of a string, merely return the given file.

Parameters

- **file** – Name or handle to a geoh5 file.
- **mode** – Set the h5 read/write mode

Return h5py.File

Handle to an opened h5py file.

`geoh5py.shared.utils.is_uuid(value: str) → bool`

Check if a string is UUID compliant.

`geoh5py.shared.utils.iterable(value: Any, checklen: bool = False) → bool`

Checks if object is iterable.

Parameters

value

[Object to check for iterableness.]

checklen

[Restrict objects with `__iter__` method to `len > 1`.]

Returns

True if object has `__iter__` attribute but is not string or dict type.

`geoh5py.shared.utils.iterable_message(valid: list[Any] | None) → str`

Append possibly iterable valid: “Must be (one of): {valid}.”.

`geoh5py.shared.utils.match_values(vec_a, vec_b, collocation_distance=0.0001) → ndarray`

Find indices of matching values between two arrays, within `collocation_distance`.

Param

`vec_a`, list or `numpy.ndarray` Input sorted values

Param

`vec_b`, list or `numpy.ndarray` Query values

Returns

indices, `numpy.ndarray` Pairs of indices for matching values between the two arrays such that `vec_a[ind[:, 0]] == vec_b[ind[:, 1]]`.

`geoh5py.shared.utils.merge_arrays(head, tail, replace='A->B', mapping=None, collocation_distance=0.0001, return_mapping=False) → ndarray`

Given two `numpy.array`s of different length, find the matching values and append both arrays.

Param

`head`, `numpy.array` of float First vector of shape(M,) to be appended.

Param

`tail`, `numpy.array` of float Second vector of shape(N,) to be appended

Param

`mapping=None`, `numpy.ndarray` of int Optional array where values from the head are replaced by the tail.

Param

`collocation_distance=1e-4`, float Tolerance between matching values.

Returns

`numpy.array` shape(O,) Unique values from head to tail without repeats, within `collocation_distance`.

`geoh5py.shared.utils.str2uuid(value: Any) → UUID | Any`

Convert string to UUID

`geoh5py.shared.utils.uuid2entity(value: UUID, workspace: Workspace) → Entity | Any`

Convert UUID to a known entity.

geoh5py.shared.validators

`class geoh5py.shared.validators.AssociationValidator(**kwargs)`

Bases: `BaseValidator`

Validate the association between data and parent object.

`classmethod validate(name: str, value: Entity | PropertyGroup | UUID | None, valid: Entity | Workspace) → None`

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Expected value shape

```
validator_type = 'association'
```

```
class geoh5py.shared.validators.AtLeastOneValidator(**kwargs)
```

Bases: *BaseValidator*

```
classmethod validate(name, value, valid)
```

Custom validation function.

```
validator_type = 'one_of'
```

```
class geoh5py.shared.validators.BaseValidator(**kwargs)
```

Bases: ABC

Concrete base class for validators.

```
abstract classmethod validate(name: str, value: Any, valid: Any)
```

Custom validation function.

```
abstract property validator_type
```

classmethod(function) -> method

Convert a function to be a class method.

A class method receives the class as implicit first argument, just like an instance method receives the instance. To declare a class method, use this idiom:

```
class C:
    @classmethod def f(cls, arg1, arg2, ...):
        ...
```

It can be called either on the class (e.g. C.f()) or on an instance (e.g. C().f()). The instance is ignored except for its class. If a class method is called for a derived class, the derived class object is passed as the implied first argument.

Class methods are different than C++ or Java static methods. If you want those, see the `staticmethod` builtin.

```
class geoh5py.shared.validators.OptionalValidator(**kwargs)
```

Bases: *BaseValidator*

Validate that forms contain optional parameter if None value is given.

```
classmethod validate(name: str, value: Any | None, valid: bool) → None
```

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – True if optional keyword in form for parameter.

```
validator_type = 'optional'
```

```
class geoh5py.shared.validators.PropertyGroupValidator(**kwargs)
```

Bases: *BaseValidator*

Validate `property_group` from parent entity.

```
classmethod validate(name: str, value: PropertyGroup, valid: str) → None
```

Custom validation function.

```
validator_type = 'property_group_type'
```

class geoh5py.shared.validators.**RequiredValidator**(**kwargs)

Bases: *BaseValidator*

Validate that required keys are present in parameter.

classmethod **validate**(name: str, value: Any, valid: bool) → None

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Assert to be required

validator_type = 'required'

class geoh5py.shared.validators.**ShapeValidator**(**kwargs)

Bases: *BaseValidator*

Validate the shape of provided value.

classmethod **validate**(name: str, value: Any, valid: tuple[int]) → None

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Expected value shape

validator_type = 'shape'

class geoh5py.shared.validators.**TypeValidator**(**kwargs)

Bases: *BaseValidator*

Validate the value type from a list of valid types.

classmethod **validate**(name: str, value: Any, valid: list[type] | type) → None

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – List of accepted value types

validator_type = 'types'

class geoh5py.shared.validators.**UUIDValidator**(**kwargs)

Bases: *BaseValidator*

Validate a uuuu.UUID value or uuid string.

classmethod **validate**(name: str, value: Any, valid: None = None) → None

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter uuid.
- **valid** – [Optional] Validate uuid from parental entity or known uuids

```
validator_type = 'uuid'
```

```
class geoh5py.shared.validators.ValueValidator(**kwargs)
```

Bases: *BaseValidator*

Validator that ensures that values are valid entries.

```
classmethod validate(name: str, value: Any, valid: list[float | str]) → None
```

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – List of accepted values

```
validator_type = 'values'
```

geoh5py.shared.weakref_utils

```
geoh5py.shared.weakref_utils.get_clean_ref(some_dict: dict[K, ReferenceType[T]], key: K) → T | None
```

Gets the referent value for the given key in a *some_dict* of *weakref* values. In case *key* points to a reference to a deleted value, remove that key from *some_dict* on the fly, and returns None.

Parameters

- **some_dict** – The dictionary of *weakref* values.
- **key** – The key

Returns

the referent value for *key* if found in the the dictionary, else None.

```
geoh5py.shared.weakref_utils.insert_once(some_dict: dict[K, ReferenceType], key: K, value)
```

Check if the reference to an Entity with uuid is already in use.

Parameters

- **some_dict** – Dictionary of UUID keys and *weakref* values.
- **key** – UUID key to be checked.
- **value** – Entity to be checked

Returns

Dictionary with clean *weakref*

```
geoh5py.shared.weakref_utils.remove_none_referents(some_dict: dict[K, ReferenceType])
```

Removes any key from the given *some_dict* where the value is a reference to a deleted value (that is where referent of the *weakref* value is None).

Parameters

some_dict – The dictionary to be cleaned up.

2.3.6 geoh5py.ui_json

geoh5py.ui_json.constants

geoh5py.ui_json.input_file

```
class geoh5py.ui_json.input_file.InputFile(data: dict[str, Any] = None, ui_json: dict[str, Any] = None,
      validations: dict = None, validation_options: dict = None,
      workspace: Workspace = None)
```

Bases: object

Handles loading ui.json input files.

Attributes

data

[Input file content parsed to flat dictionary of key:value.]

ui_json: User interface serializable as ui.json format

workspace: Target

[obj:geoh5py.workspace.Workspace]

validations: Dictionary of validations for parameters in the input file

Methods

write_ui_json()	Writes a ui.json formatted file from 'data' attribute contents.
read_ui_json()	Reads a ui.json formatted file into 'data' attribute dictionary. Optionally filters ui.json fields other than 'value'.

association_validator = <geoh5py.shared.validators.AssociationValidator object>

property data

load(input_dict: dict[str, Any])

Load data from dictionary and validate.

property name: str | None

Name of ui.json file.

classmethod numify(ui_json: dict[str, Any]) → dict[str, Any]

Convert inf, none and list strings to numerical types within a dictionary

Parameters

ui_json

dictionary containing ui.json keys, values, fields

Returns

Dictionary with inf, none and list string representations converted numerical types.

property path: str | None

Directory for the input/output ui.json file.

property path_name: str | None

static read_ui_json(*json_file: str, **kwargs*)

Read and create an InputFile from ui.json

property ui_json: dict | None

Dictionary representing the ui.json file with promoted values.

classmethod ui_validation(*ui_json: dict[str, Any]*)

Validation of the ui_json forms

update_ui_values(*data: dict, none_map=None*)

Update the ui.json values and enabled status from input data.

Parameters

- **data** – Key and value pairs expected by the ui_json.
- **none_map** – Map parameter ‘None’ values to non-null numeric types. The parameters in the dictionary are mapped to optional and disabled.

Raises

UserWarning – If attempting to set None value to non-optional parameter.

property validation_options

Pass validation options to the validators.

property validations

property validators

property workspace

write_ui_json(*name: str = None, none_map: dict[str, Any] = None, path: str = None*)

Writes a formatted ui.json file from InputFile data

Parameters

- **name** – Name of the file
- **none_map** – Map parameter None values to non-null numeric types.
- **path** – Directory to write the ui.json to.

geoh5py.ui_json.templates

geoh5py.ui_json.templates.**bool_parameter**(*main: bool = True, label: str = 'Logical data', value: bool = False*) → dict

Checkbox for true/false choice.

Parameters

- **main** – Show ui in main.
- **label** – Label identifier.
- **value** – Input value.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.choice_string_parameter`(*main: bool = True, label: str = 'String data', choice_list: tuple = ('Option A', 'Option B'), value: str = 'Option A', optional: str | None = None*) → dict

Dropdown menu of string choices.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **choice_list** – List of options.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either 'enabled' or 'disabled'.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.data_parameter`(*main: bool = True, label: str = 'Data channel', association: str = 'Vertex', data_type: str = 'Float', data_group_type: str = None, parent: str = "", value: str = "", optional: str | None = None*) → dict

Dropdown menu of data from parental object.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **association** – Data association type from 'Vertex' or 'Cell'.
- **data_type** – Type of data selectable from 'Float', 'Integer' or 'Reference'.
- **data_group_type** – [Optional] Select from property_groups of type. '3D vector', 'Dip direction & dip', 'Strike & dip', or 'Multi-element'.
- **parent** – Parameter name corresponding to the parent object.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either 'enabled' or 'disabled'.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.data_value_parameter`(*main: bool = True, label: str = 'Data channel', association: str = 'Vertex', data_type: str = 'Float', parent: str = "", value: float = 0.0, is_value: bool = True, prop: UUID | Entity | None = None, optional: str | None = None*) → dict

Dropdown of data or input box.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.

- **value** – Input value.
- **association** – Data association type from ‘Vertex’ or ‘Cell’.
- **data_type** – Type of data selectable from ‘Float’, ‘Integer’ or ‘Reference’.
- **data_group_type** – [Optional] Select from property_groups of type. ‘3D vector’, ‘Dip direction & dip’, ‘Strike & dip’, or ‘Multi-element’.
- **parent** – Parameter name corresponding to the parent object.
- **is_value** – Display the input box or dropdown menu.
- **prop** – Data entity selected in the dropdown menu if ‘is_value=False’.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.file_parameter`(*main: bool = True, label: str = 'File choices', file_description: tuple = (), file_type: tuple = (), value: str = "", optional: str | None = None*) → dict

File loader for specific extensions.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **file_description** – Title used to describe each type.
- **file_type** – Extension of files to display.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.float_parameter`(*main: bool = True, label: str = 'Float data', value: float = 1.0, vmin: float = 0.0, vmax: float = 100.0, precision: int = 2, line_edit: bool = True, optional: str | None = None*) → dict

Input box for float value.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **vmin** – Minimum value allowed.
- **vmax** – Maximum value allowed.
- **line_edit** – Allow line edit or spin box
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.integer_parameter`(*main: bool = True, label: str = 'Integer data', value: int = 1, vmin: int = 0, vmax: int = 100, optional: str | None = None*) → dict

Input box for integer value.

Parameters

- **main** – Show ui in main.
- **label** – Label identifier.
- **value** – Input value.
- **vmin** – Minimum value allowed.
- **vmax** – Maximum value allowed.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either 'enabled' or 'disabled'.

Returns

Ui_json compliant dictionary.

`geoh5py.ui_json.templates.object_parameter`(*main: bool = True, label: str = 'Object', mesh_type: tuple = (UUID('4b99204c-d133-4579-a916-a9c8b98cfccb'), UUID('19730589-fd28-4649-9de0-ad47249d9aba'), UUID('58c4849f-41e2-4e09-b69b-01cf4286cdd'), UUID('b020a277-90e2-4cd7-84d6-612ee3f25051'), UUID('9b08bb5a-300c-48fe-9007-d206f971ea92'), UUID('6a057fdc-b355-11e3-95be-fd84a7ffcb88'), UUID('7caebf0e-d16e-11e3-bc69-e4632694aa37'), UUID('77ac043c-fe8d-4d14-8167-75e300fb835a'), UUID('48f5054a-1c5c-4ca4-9048-80f36dc60a06'), UUID('e79f449d-74e3-4598-9c9c-351a28b8b69e'), UUID('b99bd6e5-4fe1-45a5-bd2f-75fc31f91b38'), UUID('849d2f3e-a46e-11e3-b401-2776bdf4f982'), UUID('4ea87376-3ece-438b-bf12-3479733ded46'), UUID('202c5db1-a56d-4004-9cad-baafd8899406'), UUID('275ecee9-9c24-4378-bf94-65f3c5fbe163'), UUID('f26feba3-aded-494b-b9e9-b2bbcbe298e1'), UUID('f495cd13-f09b-4a97-9212-2ea392aeb375'), UUID('0b639533-f35b-44d8-92a8-f70ecff3fd26'))*, *value: str = None, optional: str | None = None*) → dict

Dropdown menu of objects of specific types.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **mesh_type** – Type of selectable objects.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either 'enabled' or 'disabled'.

Returns

Ui_json compliant dictionary.

geoh5py.ui_json.templates.**optional_parameter**(state: str) → dict[str, bool]

Returns dictionary to make existing ui optional via .update() method.

Parameters

state – Initial state of optional parameter. Can be ‘enabled’ or ‘disabled’.

geoh5py.ui_json.templates.**string_parameter**(main: bool = True, label: str = ‘String data’, value: str = ‘data’, optional: str | None = None) → dict

Input box for string value.

Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input string value.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

Returns

Ui_json compliant dictionary.

geoh5py.ui_json.utils

geoh5py.ui_json.utils.**collect**(ui_json: dict[str, dict], member: str, value: Any = None) → dict[str, Any]

Collects ui parameters with common field and optional value.

geoh5py.ui_json.utils.**container_group2name**(value)

geoh5py.ui_json.utils.**dependency_requires_value**(ui_json: dict[str, dict], parameter: str) → bool

Handles dependency and optional requirements.

If dependency doesn’t require a value then the function returns False. But if the dependency does require a value, the return value is either True, or will take on the enabled state if the dependent parameter is optional.

Parameters

- **ui_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

geoh5py.ui_json.utils.**find_all**(ui_json: dict[str, dict], member: str, value: Any = None) → list[str]

Returns names of all collected parameters.

geoh5py.ui_json.utils.**flatten**(ui_json: dict[str, dict]) → dict[str, Any]

Flattens ui.json format to simple key/value pair.

geoh5py.ui_json.utils.**group_enabled**(group: dict[str, dict]) → bool

Return true if groupOptional and enabled are both true.

Parameters

group – UI.json dictionary

geoh5py.ui_json.utils.**group_optional**(ui_json: dict[str, dict], group_name: str) → bool

Returns groupOptional bool for group name.

`geoh5py.ui_json.utils.group_requires_value(ui_json: dict[str, dict], parameter: str) → bool`

True is groupOptional and group is enabled else False

Parameters

- **ui_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.inf2str(value)`

`geoh5py.ui_json.utils.is_form(var) → bool`

Return true if dictionary 'var' contains both 'label' and 'value' members.

`geoh5py.ui_json.utils.is_uijson(ui_json: dict[str, dict])`

Returns True if dictionary contains all the required parameters.

`geoh5py.ui_json.utils.list2str(value)`

`geoh5py.ui_json.utils.monitored_directory_copy(directory: str, entity: ObjectBase, copy_children: bool = True)`

Create a temporary geoh5 file in the monitoring folder and export entity for update.

Parameters

- **directory** – Monitoring directory
- **entity** – Entity to be updated
- **copy_children** – Option to copy children entities.

`geoh5py.ui_json.utils.none2str(value)`

`geoh5py.ui_json.utils.optional_requires_value(ui_json: dict[str, dict], parameter: str) → bool`

True if enabled else False.

Parameters

- **ui_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.path2workspace(value)`

`geoh5py.ui_json.utils.requires_value(ui_json: dict[str, dict], parameter: str) → bool`

Check if a ui.json parameter requires a value (is not optional).

The required status of a parameter depends on a hierarchy of ui switches. At the top is the groupOptional switch, below that is the dependency switch, and on the bottom is the optional switch. When group optional is disabled all parameters in the group are not required, When the groupOptional is enabled the required status of a parameter depends first any dependencies and lastly on it's optional status.

Parameters

- **ui_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.set_enabled(ui_json: dict, parameter: str, value: bool)`

Set enabled status for an optional or groupOptional parameter.

Parameters

- **ui_json** – UI.json dictionary

- **parameter** – Parameter name.
- **value** – Boolean value set to parameter’s enabled member.

geoh5py.ui_json.utils.**str2inf**(*value*)

geoh5py.ui_json.utils.**str2list**(*value*)

geoh5py.ui_json.utils.**str2none**(*value*)

geoh5py.ui_json.utils.**truth**(*ui_json: dict[str, dict], name: str, member: str*) → bool

Return parameter’s ‘member’ value with default value for non-existent members.

geoh5py.ui_json.utils.**workspace2path**(*value*)

geoh5py.ui_json.validation

```
class geoh5py.ui_json.validation.InputValidation(validators: dict[str, BaseValidator] = None,  
                                                validations: dict[str, Any] | None = None,  
                                                workspace: Workspace = None, ui_json: dict[str,  
                                                Any] | None = None, validation_options: dict[str,  
                                                Any] | None = None)
```

Bases: object

Validations on dictionary of parameters.

Attributes

validations

[Validations dictionary with matching set of input parameter keys.]

workspace (optional)

[Workspace instance needed to validate uuid types.]

ignore_requirements (optional): Omit raising error on ‘required’ validator.

Methods

validate_data(data)	Validates data of params and contents/type/shape/keys/reqs of values.
----------------------------	---

```
static infer_validations(ui_json: dict[str, Any] | None, validations: dict[str, dict] | None = None) →  
dict
```

Infer necessary validations from ui json structure.

```
validate(name: str, value: Any, validations: dict[str, Any] = None)
```

Run validations on a given key and value.

Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **validations** – [Optional] Validations provided on runtime

validate_data(*data: dict[str, Any]*) → None

Calls validate method on individual key/value pairs in input.

Parameters

data – Input data with known validations.

property validations

property validators

property workspace

2.3.7 geoh5py.workspace

geoh5py.workspace.workspace

```
class geoh5py.workspace.workspace.Workspace(h5file: str | Path | io.BytesIO = 'Analyst.geoh5', mode='a',
                                             **kwargs)
```

Bases: AbstractContextManager

The Workspace class manages all Entities created or imported from the *geoh5* structure.

The basic requirements needed to create a Workspace are:

Parameters

geoh5 – File name of the target *geoh5* file. A new project is created if the target file cannot be found on disk.

activate()

Makes this workspace the active one.

In case the workspace gets deleted, `Workspace.active()` safely returns None.

static active() → *Workspace*

Get the active workspace.

property attribute_map: dict

Mapping between names used in the *geoh5* database.

close()

Close the file and clear properties for future open.

property contributors: ndarray

`numpy.array` of `str` List of contributors name.

copy_to_parent(*entity, parent, copy_children: bool = True, omit_list: tuple = ()*)

Copy an entity to a different parent with copies of children.

Parameters

- **entity** – Entity to be copied.
- **parent** – Target parent to copy the entity under.
- **copy_children** – Copy all children of the entity.
- **omit_list** – List of property names to omit on copy

Returns

The Entity registered to the workspace.

create_data(*entity_class*, *entity_kwargs*: dict, *entity_type_kwargs*: dict | *DataType*) → *Data* | None

Create a new Data entity with attributes.

Parameters

- **entity_class** – *Data* class.
- **entity_kwargs** – Properties of the entity.
- **entity_type_kwargs** – Properties of the entity_type.

Returns

The newly created entity.

create_entity(*entity_class*, *save_on_creation*: bool = True, ***kwargs*) → *Entity* | None

Function to create and register a new entity and its entity_type.

Parameters

- **entity_class** – Type of entity to be created
- **save_on_creation** – Save the entity to geoh5 immediately

Return entity

Newly created entity registered to the workspace

create_from_concatenation(*attributes*)

create_object_or_group(*entity_class*, *entity_kwargs*: dict, *entity_type_kwargs*: dict) → *Group* | *ObjectBase* | None

Create an object or a group with attributes.

Parameters

- **entity_class** – *ObjectBase* or *Group* class.
- **entity_kwargs** – Attributes of the entity.
- **entity_type_kwargs** – Attributes of the entity_type.

Returns

A new Object or Group.

property data: list[*data.Data*]

Get all active Data entities registered in the workspace.

deactivate()

Deactivate this workspace if it was the active one, else does nothing.

property distance_unit: str

str Distance unit used in the project.

fetch_array_attribute(*entity*: *Entity*, *key*: str = 'cells') → ndarray

Fetch attribute stored as structured array from the source geoh5.

Parameters

- **entity** – Unique identifier of target entity.
- **file** – h5py.File or name of the target geoh5 file
- **key** – Field array name

Returns

Structured array.

fetch_children(*entity*: Entity | None, *recursively*: bool = False) → list

Recover and register children entities from the geoh5.

Parameters

- **entity** – Parental entity.
- **recursively** – Recover all children down the project tree.
- **file** – h5py.File or name of the target geoh5 file.

Return list

List of children entities.

fetch_concatenated_attributes(*entity*: Group | ObjectBase) → dict | None

Fetch attributes of Concatenated entities.

Parameters

entity – Concatenator group.

Returns

Dictionary of attributes.

fetch_concatenated_list(*entity*: Group | ObjectBase, *label*: str) → list | None

Fetch list of data or indices of Concatenated entities.

Parameters

- **entity** – Concatenator group.
- **label** – Label name of the h5py.Group

Returns

List of concatenated Data names.

fetch_concatenated_values(*entity*: Group | ObjectBase, *label*: str) → tuple | None

Fetch data under the Concatenated Data group of an entity.

Parameters

- **entity** – Concatenator group.
- **label** – Name of the target data.

Returns

Index array and data values for the target label.

fetch_file_object(*uid*: uuid.UUID, *file_name*: str) → bytes | None

Fetch an image from file name.

Parameters

uid – Unique identifier of target data object.

Returns

Array of values.

fetch_metadata(*uid*: uuid.UUID, *argument*='Metadata') → dict | None

Fetch the metadata of an entity from the source geoh5.

Parameters

- **uid** – Entity uid containing the metadata.
- **argument** – Optional argument for other json-like attributes.

Returns

Dictionary of values.

fetch_or_create_root()

fetch_property_groups(*entity: Entity*) → list[*PropertyGroup*]

Fetch all property_groups on an object from the source geoh5

Parameters

entity – Target object

Returns

List of PropertyGroups

fetch_type(*uid: UUID, entity_type: str*) → dict

Fetch attributes of a specific entity type. :param uid: Unique identifier of the entity type. :param entity_type: One of ‘Data’, ‘Object’ or ‘Group’

fetch_values(*entity: Entity*) → np.ndarray | str | float | None

Fetch the data values from the source geoh5.

Parameters

entity – Entity with ‘values’.

Returns

Array of values.

finalize() → None

Deprecate method finalize

Parameters

file – h5py.File or name of the target geoh5 file

find_data(*data_uid: uuid.UUID*) → *Entity* | None

Find an existing and active Data entity.

find_entity(*entity_uid: uuid.UUID*) → *Entity* | None

Get all active entities registered in the workspace.

find_group(*group_uid: uuid.UUID*) → *group.Group* | None

Find an existing and active Group object.

find_object(*object_uid: uuid.UUID*) → *object_base.ObjectBase* | None

Find an existing and active Object.

find_type(*type_uid: uuid.UUID, type_class: type[EntityType]*) → *EntityType* | None

Find an existing and active EntityType

Parameters

type_uid – Unique identifier of target type

property ga_version: str

str Version of Geoscience Analyst software.

property geoh5: File

Instance of h5py.File.

get_entity(*name: str | uuid.UUID*) → list[*Entity* | None]

Retrieve an entity from one of its identifier, either by name or uuid.UUID.

Parameters

name – Object identifier, either name or uuid.

Returns

List of entities with the same given name.

property groups: list[groups.Group]

Get all active Group entities registered in the workspace.

property h5file: str | Path | io.BytesIO

Str

Target *geoh5* file name with path.

property list_data_name: dict[uuid.UUID, str]

dict of uuid.UUID keys and name values for all registered Data.

property list_entities_name: dict[uuid.UUID, str]

Returns

dict of uuid.UUID keys and name values for all registered Entities.

property list_groups_name: dict[uuid.UUID, str]

dict of uuid.UUID keys and name values for all registered Groups.

property list_objects_name: dict[uuid.UUID, str]

dict of uuid.UUID keys and name values for all registered Objects.

load_entity(*uid: uuid.UUID, entity_type: str, parent: Entity = None*) → *Entity* | None

Recover an entity from geoh5.

Parameters

- **uid** – Unique identifier of entity
- **entity_type** – One of entity type ‘group’, ‘object’, ‘data’ or ‘root’

Return entity

Entity loaded from geoh5

property name: str

str Name of the project.

property objects: list[objects.ObjectBase]

Get all active Object entities registered in the workspace.

open(*mode: str | None = None*) → *Workspace*

Open a geoh5 file and load the tree structure.

Parameters

mode – Optional mode of h5py.File. Defaults to ‘r+’.

Returns

self

remove_children(*parent, children: list*)

Remove a list of entities from a parent.

remove_entity(*entity: Entity*)

Function to remove an entity and its children from the workspace

remove_none_referents(*referents: dict[uuid.UUID, ReferenceType], rtype: str*)

Search and remove deleted entities

remove_recursively(*entity: Entity*)

Delete an entity and its children from the workspace and geoh5 recursively

property repack: bool

Flag to repack the file after data deletion

property root: Entity | None

RootGroup entity.

save_entity(*entity: Entity, add_children: bool = True*) → None

Save or update an entity to geoh5.

Parameters

- **entity** – Entity to be written to geoh5.
- **add_children** – Add children entities to geoh5.
- **file** – *h5py.File* or name of the target geoh5

property types: list[EntityType]

Get all active entity types registered in the workspace.

update_attribute(*entity: Entity | EntityType, attribute: str, channel: str = None, **kwargs*) → None

Save or update an entity to geoh5.

Parameters

- **entity** – Entity to be written to geoh5.
- **attribute** – Name of the attribute to get updated to geoh5.
- **channel** – Optional channel argument for concatenated data and index.

property version: float

float Version of the geoh5 file format.

property workspace: Workspace

This workspace instance itself.

`geoh5py.workspace.workspace.active_workspace(workspace: Workspace)`

2.4 GEOH5 Format

2.4.1 About

The GEOH5 format aims to provide a

ro-
bust
means
of
han-
dling
large
quan-
ti-
ties
of
di-
verse
data
re-
quired
in
geo-
science.
The
file
struc-
ture
builds
on
the
generic
qual-
i-
ties
of
the

Geoscience ANALYST data model, and attempts to maintain a certain level of simplicity and consistency throughout. It is based entirely on free and open [HDF5 technology](#). Given that this specification is public, the file format could, with further investment and involvement, become a useful exchange format for the broader geoscientific community.

Why GEOH5?

- **Leverages properties**
Fast
I/O,
com-
pres-
sion,
cross-
platform
- **Content readable and**
We
rec-
om-
mend
us-
ing

HD-FView, along with Geoscience AN-A-LYST, when learning the format.

- **Easily extensible to**

It is intended for Geoscience AN-A-LYST to preserve data it does not understand (and generally be very tolerant with regards to missing information).

ma-
tion)
when

loading and saving geoh5 files. This will allow third parties to write to this format fairly easily, as well as include additional information not included in this spec for their own purposes. In the current implementation, Geoscience ANALYST automatically removes unnecessary information on save.

2.4.2 Defin

The
fol-
low-
ing
sec-
tions

Root

Op-
tional

hard link to workspace group, top of group hierarchy.

Types

- *Data Types:* Flat container for all data types
- *Group Types:* Flat container for all group types
- *Object Types:* Flat container for all object types

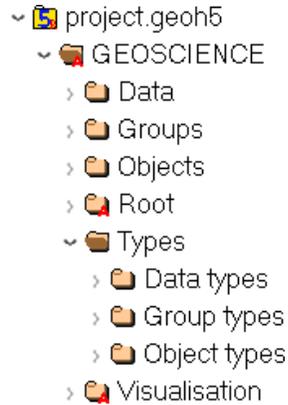

Fig. 2.1: As seen in HD-FView

While all groups, objects and data entities are written into their respective base folder, they also hold links to their children entities to allow for traversals. There is no data duplication, merely multiple references (pointers) to the data storage on file. Types are shared (and thus generally written to file first). All groups, objects and data must include a hard link to their type.

Attributes

Version

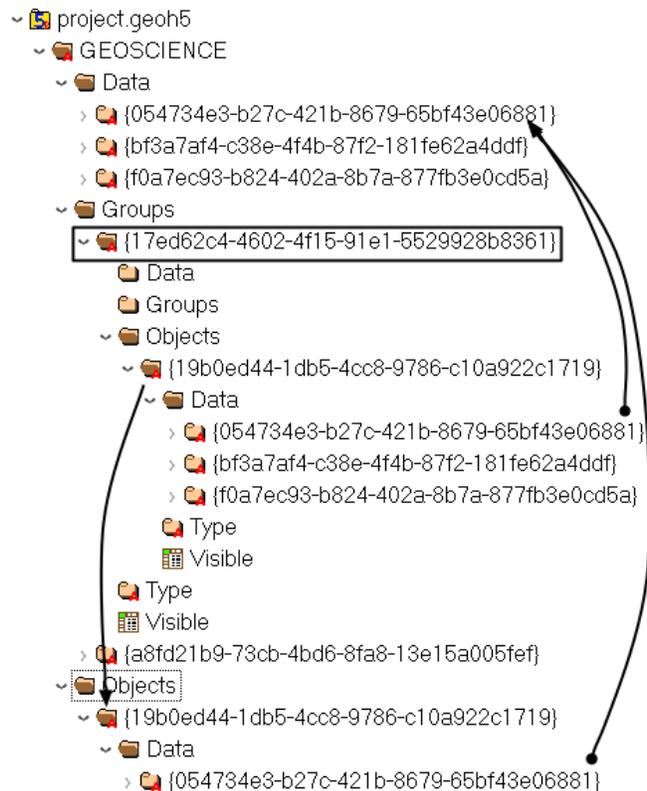

`double` Version of specification used by this file

Distance unit

`str` *feet* or (default) *metres* Distance unit of all data enclosed

Contributors

1D array of `str` (Optional) List of users who contributed to this workspace

Groups

Groups are simple container for other groups and objects. They are often used to assign special meanings to a collection of entities or to create specialized software functionality.

Attributes

Name

str Name of the object displayed in the project tree.

ID

str, *UUID* Unique identifier of the group.

Visible

int, 0 or (default) 1 Set visible in the 3D camera (checked in the object tree).

Public

int, 0 or (default) 1 Set accessible in the object tree and other parts of the the user interface.

Clipping IDs

1D array of *UUID* (Optional) List of unique identifiers of clipping plane objects.

Allow delete

int, 0 or (default) 1 (Optional) User interface allows deletion.

Allow move

int, 0 or (default) 1 (Optional) User interface allows moving to another parent group.

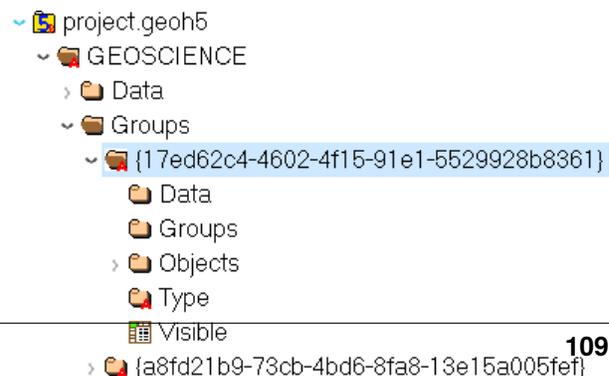

Allow rename

int, 0 or (default) 1 (Optional) User interface allows renaming.

Metadata

(int, optional) (Optional) Any additional text attached to the group.

The following section describes the supported group types.

Group Types

To be further documented

Container

UUID : {61FBB4E8-A480-11E3-8D5A-2776BDF4F982}

Simple container with no special meaning. Default in Geoscience ANALYST.

Drillholes

UUID : {825424FB-C2C6-4FEA-9F2B-6CD00023D393}

Container restricted to containing drillhole objects, and which may provide convenience functionality for the drillholes within.

No Type (Root)

UUID : {dd99b610-be92-48c0-873c-5b5946ea2840}

The Root group defines the tree structure used in Geoscience ANALYST describing the parent-child relationships of entities. If absent, any Groups/Objects/Data will be brought into Geoscience ANALYST under the workspace group, still respecting any defined hierarchy links.

SimPEG

UUID : {55ed3daf-c192-4d4b-a439-60fa987fe2b8}

Container group for SimPEG inversions. Contains

Datasets

Metadata

json formatted string

Dictionary of inversion options.

options

Note: Though this file format technically allows objects/groups to appear within multiple groups simultaneously (overlapping lists), this is not currently supported by Geoscience ANALYST.

Objects

Objects are containers for Data with spatial information. Most (not all) object geometry is described in terms of vertices (3D locations) and cells (groupings of vertices such as triangles or segments). The exact requirements and interpretation depends on the type.

Attributes

Name

str Name of the object displayed in the project tree.

ID

str Unique identifier (*UUID*) of the group.

Visible

int, 0 or (default) 1 Set visible in the 3D camera (checked in the object tree).

Public

int, 0 or (default) 1 Set accessible in the object tree and other parts of the the user interface.

Clipping IDs

1D array of UUID (Optional) List of unique identifiers of clipping plane objects.

Allow delete

int, 0 or (default) 1 (Optional) User interface allows deletion.

Allow move

int, 0 or (default) 1 (Optional) User interface allows moving to another parent group.

Allow rename

int, 0 or (default) 1 (Optional) User interface allows renaming.

Metadata

(int, optional) (Optional) Any additional text attached to the group.

The following section describes the supported object types and their specific attributes.

ANALYST Objects

Entities with spatial information used to store data.

Points

UUID : {202C5DB1-A56D-4004-9CAD-BAAFD8899406}

3-D scatter points object defined by vertices with fixed coordinates in Cartesian system (x, y and z).

Datasets

Vertices

1D composite array

[x double, y double, z double]

Curve

UUID : {6A057FDC-B355-11E3-95BE-FD84A7FFCB88}

Polyline object defined by a series of line segments (cells) connecting vertices. Data can be associated to either the vertices or cells.

Attributes

Current line property ID

str, *UUID*

Unique identifier of a reference data for naming of curve parts.

Datasets

Cells

Array of `int32`, shape(N, 2)

Array defining the connection (line segment) between pairs of vertices.

Surface

UUID : {F26FEBA3-ADED-494B-B9E9-B2BBCBE298E1}

Triangulated mesh object defined by cells (triangles) and vertices.

Datasets

Cells

Array of `int32`, shape(N, 3)

Array defining the connection between triplets of vertices, representing triangles.

Block model

UUID : {B020A277-90E2-4CD7-84D6-612EE3F25051}

Rectilinear grid of cells defined along three orthogonal axes (U,V and Z) of length nU, nV and nZ respectively. The conversion between the array coordinates of a cell to a 1-D vector index can be calculated from

$$\text{cell index} = k + i * nZ + j * nU * nZ$$

Without rotation angles, U points eastwards, V points northwards, and Z points upwards. Since their geometry is defined entirely by the additional data described below, block models do not require a `Vertices` or `Cells` dataset.

Datasets

U cell delimiters

array of `double`, shape(nU,)

Distances of cell edges from origin along the U axis (first value should be 0)

V cell delimiters

array of `double`, shape(nV,)

Distances of cell edges from origin along the V axis (first value should be 0)

Z cell delimiters

array of double, shape(nZ,)

Distances of cell edges from origin upwards along the vertical axis (first value should be 0)

Attributes

Origin

composite type

[X double, Y double, Z double]

Origin point of grid

Rotation

double (default) 0 Counterclockwise angle (degrees) of rotation around the vertical axis in degrees.

2D Grid

UUID : {48f5054a-1c5c-4ca4-9048-80f36dc60a06}

Rectilinear grid of cells defined along two orthogonal axes (U and V) of length nU and nV. The conversion between the grid coordinates of a cell to its 1-D vector index can be calculated from

$\text{cell index} = i + j * nU$

Without rotation angles, U points eastwards and V points northwards. Since their geometry is defined entirely by the additional data described below, 2D grids do not require a Vertices or Cells dataset.

Attributes

Origin

composite type

[X double, Y double, Z double]

Origin point of the grid.

U Size

double Length of U axis

U Count

double Number of cells along U axis

V Size

double Length of V axis

V Count

double Number of cells along V axis

Rotation

double (Optional) Counterclockwise angle (degrees) of rotation around the vertical axis at the Origin.

Vertical

char, 0(false, default) or 1(true)) (Optiona) If true, V axis is vertical (and rotation defined around the V axis)

Drillhole

UUID : {7CAEBF0E-D16E-11E3-BC69-E4632694AA37}

Object representing boreholes defined by a collar location and survey parameters. Vertices represent points along the drillhole path (support for data rather than the drillhole geometry itself) and must have a `Depth` property value. Cells contain two vertices and represent intervals along the drillhole path (and are a support for interval data as well). Cells may overlap with each other to accommodate the different sampling intervals of various data.

Attributes

Collar

composite type, shape(3,)

[*X* double, *Y* double, *Z* double]

Collar location

Datasets

Surveys

composite array, shape(3,)

[*Depth* double, *Dip* double, *Azimuth* double]

Survey locations

Trace

1D composite array

[*X* double, *Y* double, *Z* double]

Points forming the drillhole path from collar to end of hole. Must contain at least two points.

Geoimage

UUID : {77AC043C-FE8D-4D14-8167-75E300FB835A}

Not yet geoh5py implemented

To be further documented

Vertices represent the four corners of the geolocated image. No cell data. An object-associated file-type data containing the image to display is expected to exist under this object.

Note: Should be arranged as a rectangle currently, since Geoscience ANALYST does not currently support skewed images.

Label

UUID : {E79F449D-74E3-4598-9C9C-351A28B8B69E}

Not yet geoh5py implemented

To be further documented

Has no vertices nor cell data

Attributes

Target position

composite type, shape(3,)

[X double, Y double, Z double]

The target location of the label

Label position

composite type, shape(3,)

[X double, Y double, Z double] (Optional - Defaults to same as target position) The location where the text of the label is displayed

Slicer

UUID : {238f961d-ae63-43de-ab64-e1a079271cf5}

Not yet geoh5py implemented

To be further documented

Target

UUID : {46991a5c-0d3f-4c71-8661-354558349282}

Not yet geoh5py implemented

To be further documented

ioGAS Points

UUID : {d133341e-a274-40e7-a8c1-8d32fb7f7eaf}

Not yet geoh5py implemented

To be further documented

Maxwell Plate

UUID : {878684e5-01bc-47f1-8c67-943b57d2e694}

Not yet geoh5py implemented

To be further documented

Octree

UUID : {4ea87376-3ece-438b-bf12-3479733ded46}

Semi-structured grid that stores cells in a tree structure with eight octants.

Datasets

Octree Cells

composite type, shape(N, 4)

[*I* integer, *J* integer, *K* integer, *NCells* integer]

Array defining the position (I, J, K) and size (NCells) of every cell within the base octree grid.

Attributes

NU

integer Number of base cells along the U-axis.

NV

integer Number of base cells along the V-axis.

NW

integer Number of base cells along the W-axis.

Origin

composite type, shape(3,)

[*X* double, *Y* double, *Z* double]

Origin point of the grid.

Rotation

double (default) 0 Counterclockwise angle (degrees) of rotation around the vertical axis in degrees.

U Cell Size

double Base cell dimension along the U-axis.

V Cell Size

double Base cell dimension along the V-axis.

W Cell Size

double Base cell dimension along the W-axis.

Text Object

UUID : {c00905d1-bc3b-4d12-9f93-07fcf1450270}

Not yet geoh5py implemented

To be further documented

Potential Electrode

UUID : {275ecee9-9c24-4378-bf94-65f3c5fbe163}

Curve object representing the receiver electrodes of a direct-current resistivity survey.

Datasets

Metadata

json formatted string

Dictionary defining the link between the source and receiver objects.

- “Current Electrodes” uuid: Identifier for the linked *Current Electrode*
- “Potential Electrodes” uuid: Identifier for the linked *Potential Electrode*

Requirements

A-B Cell ID

Data entity

Reference data named “A-B Cell ID” with association=CELL expected. The values define the source dipole (cell) from the *Current Electrode* to every potential measurement.

Current Electrode

UUID : {9b08bb5a-300c-48fe-9007-d206f971ea92}

Curve object representing the transmitter electrodes of a direct-current resistivity survey.

Datasets

Metadata

json formatted string

Dictionary defining the link between the source and receiver objects. Same definition as the *Potential Electrode* object.

Requirements

A-B Cell ID

Data entity

Reference data named “A-B Cell ID” with `association=CELL` defining a unique identifier to every unique dipole sources. For “pole” sources, the `cell` attribute references twice to the same vertex.

VP Model

UUID : {7d37f28f-f379-4006-984e-043db439ee95}

Not yet geoh5py implemented

To be further documented

Airborne EM

UUID : {fdf7d01e-97ab-43f7-8f2c-b99cc10d8411}

Not yet geoh5py implemented

To be further documented

Airborne TEM Rx

UUID : {19730589-fd28-4649-9de0-ad47249d9aba}

Curve object representing an array of time-domain electromagnetic receiver dipoles.

Attributes

Target position

composite type

Datasets

Metadata

json formatted string

Dictionary of survey parameters shared with the *Transmitters*. The following items are core parameters stored under the “EM Dataset” key.

- **“Channels”:** list of double
Time channels at which data are recorder.
- **“Input type”:** string
Type of survey from “Rx”, “Tx” or “Tx and Rx”
- **“Loop radius”:** double
Transmitter loop radius.
- **“Property groups”:** list of uuid
Reference to property groups containing data at every channel.

- **“Receivers”:** **uuid**
Unique identifier referencing to itself.
- **“Survey type”:** **string**
Defaults to “Airborne TEM”.
- **“Transmitters”:** **uuid**
Unique identifier referencing to the linked transmitters entity.
- **“Unit”:** **string**
Sampling units, must be one of “Seconds (s)”, “Milliseconds (ms)”, “Microseconds (us)” or “Nanoseconds (ns)”.
- **“Crossline offset property” uuid OR “Crossline offset value” double:**
Offline offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- **“Inline offset property” uuid OR “Crossline offset value” double:**
Inline offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- **“Inline offset property” uuid OR “Crossline offset value” double:**
Vertical offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- **“Yaw property” uuid OR “Yaw value” double:**
Rotation (angle) of the transmitter loop as measured on the UV-plane (+ clockwise), either defined locally on vertices as a property OR globally as a constant value.
- **“Pitch property” uuid OR “Pitch value” double:**
Tilt angle of the transmitter loop as measured on the VW-plane (+ nose up), either defined locally on vertices as a property OR globally as a constant value.
- **“Roll property” uuid OR “Roll value” double:**
Banking angle of the transmitter loop as measured on the UW-plane (+ right-wing down), either defined locally on vertices as a property OR globally as a constant value.
- **“Waveform” dict:**
 - **“Discretization” array of double, shape(N, 2):**
Array of times and normalized currents (Amp) describing the source impulse over a discrete interval (e.g. [[t_1, c_1], [t_2, c_2], ..., [t_N, c_N]])
 - **“Timing mark” double:**
Reference timing mark measured from the beginning of the “Discretization”. Generally used as the reference (t_i=0.0) for the provided data channels: (-) on-time an (+) off-time.

Airborne TEM Tx

UUID : {58c4849f-41e2-4e09-b69b-01cf4286cded}

Curve object representing an array of time-domain electromagnetic transmitter loops.

Datasets

Metadata

json formatted string

See definition from the *Airborne TEM Rx* object. The “Transmitters” uuid value should point to itself, while the “Receivers” uuid refers the linked *Airborne TEM Rx* object.

Magnetotellurics

UUID : {b99bd6e5-4fe1-45a5-bd2f-75fc31f91b38}

Points object representing a magnetotelluric survey.

Metadata

json formatted string

Dictionary of survey parameters. The following items are core parameters stored under the “EM Dataset” key.

- **“Channels”**: **list of double**
Frequency channels at which data are recorder.
- **“Input type”**: **string**
Static field set to “Rx only”
- **“Property groups”**: **list of uuid**
Reference to property groups containing data at every channel.
- **“Receivers”**: **uuid**
Reference to itself.
- **“Survey type”**: **string**
Static field set to “Magnetotellurics”
- **“Unit”**: **string**
Sampling units, must be one of “Hertz (Hz)”, “KiloHertz (kHz)”, “MegaHertz (MHz)” or “Gigahertz (GHz)”.

Tipper Rx

UUID : {0b639533-f35b-44d8-92a8-f70ecff3fd26}

Curve object representing a tipper survey.

Metadata

json formatted string

Dictionary of survey parameters. The following items are core parameters stored under the “EM Dataset” key.

- **“Channels”**: list of double
Frequency channels at which data are recorder.
- **“Input type”**: string
Static field set to “Rx and base stations”
- **“Property groups”**: list of uuid
Reference to property groups containing data at every channel.
- **“Receivers”**: uuid
Reference to itself.
- **“Base stations”**: uuid
Reference to *Tipper Base stations*
- **“Survey type”**: string
Static field set to “Magnetotellurics”
- **“Unit”**: string
Sampling units, must be one of “Hertz (Hz)”, “KiloHertz (kHz)”, “MegaHertz (MHz)” or “Gigahertz (GHz)”.

Tipper Base stations

UUID : {f495cd13-f09b-4a97-9212-2ea392aeb375}

Points object representing a tipper survey.

Metadata

json formatted string

See definition from the *Tipper Rx* object. The “Base stations” uuid value should point to itself, while the “Receivers” uuid refers the linked *Tipper Rx* object.

Data

Containers for data values of various types. Data are currently **always stored as a 1D array**, even in the case of single-value data with the Object association (in which case it is a 1D array of length 1). See the [Data Types](#) section for the list of supported data types.

Attributes

Association

str Describes which part the property is tied to. Must be one of: *Unknown, Object, Cell, Vertex, Face* or *Group*

Name

str Name of the data displayed in the project tree.

ID

str Unique identifier (*UUID*) of the group.

Visible

int, 0 or 1 (Optional) Set visible in the 3D camera (checked in the object tree).

Clipping IDs

1D array of UUID (Optional) List of unique identifiers of clipping plane objects.

Allow delete

int, 0 or (default) 1 (Optional) User interface allows deletion.

Allow rename

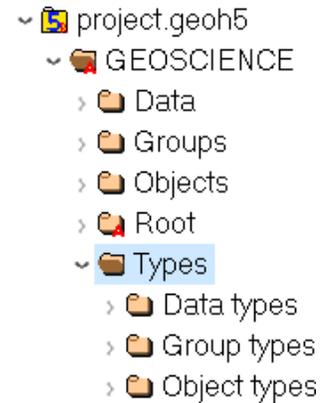

int, 0 or (default) 1 (Optional) User interface allows renaming.

Public

int, 0 or (default) 1 (Optional) Set accessible in the object tree and other parts of the the user interface.

Types

While they are structured similarly, **each group, object or set of data has a type that defines how its HDF5 datasets should be interpreted.** This type is shared among any number of entities (groups/objects/data sets).

Group Types

Attributes

Name

str Name of the group displayed in the project tree.

ID

str Unique identifier (*UUID*) of the group type.

Description

str (Optional) Description of the type.

Allow move contents

int, 0 or (default) 1 (Optional) User interface allows deletion of the content.

Allow delete contents

int, 0 or (default) 1 (Optional) User interface allows deletion of the content.

Object Types

Objects are containers for data values with spatial information.

Attributes

Name

str Name of the object displayed in the project tree.

ID

str Unique identifier (*UUID*) of the group type.

Description

str (Optional) Description of the type.

Data Types

New data types can be created at will by software or users to describe object or group properties. Data of the same type can exist on any number of objects or groups of any type, and each instance can be associated with vertices, cells or the object/group itself. Some data type identifiers can also be reserved as a means of identifying a specific kind of data.

Attributes

Name

str Name of the object displayed in the project tree.

ID

str Unique identifier (*UUID*) of the data type.

Unlike Groups and Objects, Data entities do not generally have fixed identifier Type. Multiple data entities linked by a type will share common properties (color map, units, etc.). Exceptions to this rule are the fixed:

Primitive type

`str`

Specifies the kind of data values stored as HDF5 dataset. Must be one of:

Primitive Types

To be further documented

Float

- Stored as a 1D array of 32-bit float type
- No data value: 1.175494351e-38 (FLT_MIN, considering use of NaN)

Integer

- Stored as a 1D array of 32-bit integer type
- No data value: -2147483648 (INT_MIN, considering use of NaN)

Text

- Stored as a 1D array of UTF-8 encoded, variable-length string type
- No data value : empty string

Referenced

- Stored as a 1D array of 32-bit unsigned integer type (native)
- Value map : (1D composite type array dataset - Key (unsigned int), Value (variable-length utf8 string)) must exist under type
- No data value : 0 (key is tied to value “Unknown”)

DateTime

- Stored as a 1D array of variable-length strings formatted according to the [ISO 8601](#) extended specification for representations of UTC dates and times (Qt implementation), taking the form YYYY-MM-DDTHH:mm:ss[Z][+/-]HH:mm
- No data value : empty string

Filename

- Stored as a 1D array of UTF-8 encoded, variable-length string type designating a file name
- For each file name within “Data”, an opaque dataset named after the filename must be added under the Data instance, containing a complete binary dump of the file
- Different files (under the same object/group) must be saved under different names
- No data value : empty string

Blob

- Stored as a 1D array of 8-bit char type (native) (value '0' or '1')
- For each index set to 1, an opaque dataset named after the index (e.g. "1", "2", etc) must be added under the Data instance, containing the binary data tied to that index
- No data value : 0

Description

str (Optional) Description of the type.

Units

str (Optional) Data units

Color map

1D compound array

[*Value* double, *Red* uint, *Green* uint, *Blue* uint, *Alpha* uint]

(Optional) Records colors assigned to value ranges. The *Value* mark the start of the range)

Value map

(1D compound array dataset)

[*Key* uint, *Value* str]

Required only for reference data types (classifications)

Transparent no data

int, 0 or (default) 1 (Optional) Whether or not absence of data/filtered data should be hidden in the viewport.

Hidden

int, 0 or (default) 1 (Optional) Whether or not the data type should appear in the data type list.

Scientific notation

int, 0 or (default) 1 (Optional) Whether or not the data values of this type should be displayed in scientific notation.

Precision

int (Optional) The number of decimals (or significant digits in case of scientific notation) used when displayed data values of this type.

Number of bins

int, default=50 (Optional) Number of bins used when displaying histogram

Duplicate type on copy

int, 0 or (default) 1 (Optional) When enabled, a separate copy of this data type will be created and used when data of this type is copied.

2.4.3 Standards

General notes on formatting.

- All text data and attributes are variable-length and use UTF-8 encoding
- All numeric data uses INTEL PC native types
- Boolean values are stored using char (0:false, 1:true)
- Anything found in a geoh5 v1.0 file which is not mentioned in this document is optional information

2.5 UI.JSON Format

2.5.1 About

The **ui.json** format provides a User Interface (UI) between geoh5py and Geoscience ANALYST Pro. The file structure is built on an array of **JSON objects**, each representing a parameter that is used in a python script. An object contains members that control the style and behaviour of the UI. In general only a **label** and **value** member is required in each object, however as outlined below, there are many types of input and dependencies that can be drawn on throughout the file. On output from Geoscience ANALYST, the value and whether the parameter is enabled will be updated or added to each JSON. Extra objects in the JSON are allowed and are ignored, but written out by Geoscience ANALYST. In general, objects will be put in order that they are set in the JSON. The exception is data parameters that depend on object parameters. Placing those parameters in the same group will ensure that they are close in the UI.

2.5.2 Input Objects

Within the **ui.json** file, each JSON object with **value** and **label** members will be considered a parameter to the UI. The following JSON objects could also be present:

run_command str

Name of python script excluding the .py extension (i.e., “run_me” for run_me.py) required for Geoscience ANALYST Pro to run on save or auto-load.

conda_environment str

Optional name of conda environment to activate when running the python script in *run_command*

title str

Optional title of user interface window

2.5.3 Object Members

Each JSON object with the following members become a parameter in the user interface. Each object must have the members `label` and `value`. Each member will contribute to the appearance and behaviour within Geoscience ANALYST>. The possible members that can be given to all parameter objects are:

label str

Required string describing parameter. A colon will automatically be added within Geoscience ANALYST, so this should be omitted.

value str, int, bool , or float

This require member takes a different form, including empty, depending on the *parameter type*. The value is updated when written from Geoscience ANALYST.

main bool

If set to true, the parameter is shown in the first tab and will throw an error if not given and not optional. Optional parameters may be set to main. When main is not given or is false, the parameter will be under the *Optional Parameters* tab.

tooltip str

String describing the parameter in detail that appears when the mouse hovers over it.

optional bool

true or *false* on whether the parameter is optional. On output, check if *enabled* is set to true.

enabled bool

true or *false* if the parameter is enabled. The default is true. If a parameter is optional and not enabled, it will start as disabled (grey and inactive in the UI).

group str

Name of the group to which the parameter belongs. Adds a box and name around the parameters with the same case-sensitive group name.

groupOptional bool

If true, adds a checkbox in the top of the group box next to the name. The group parameters will be disabled if not checked. The initial statedpends on the **groupDependency** and **groupDependencyType** members and the **enabled** member of the group's parameters.

dependency str

The name of the object of which this object is dependent upon. The dependency parameter should be optional or boolean parameter (i.e., has a checkbox).

dependencyType str

What happens when the dependency member is checked. Options are *enabled* or *disabled*

groupDependency str

The name of the object of which the group of the parameter is dependent upon. This member will also require the **groupOptional** member to be present and set to *true*. Be sure that the object is not within the group.

groupDependencyType str

What happens when the group's dependency parameter is checked. Options are *enabled* or *disabled*.

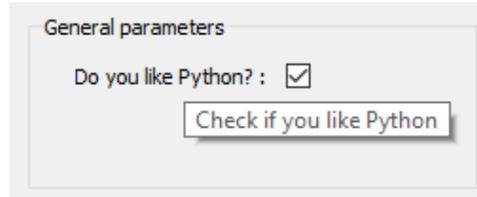

2.5.4 Parameter Types

There are other JSON members that may be available or required based on the parameter type. The following sections define different parameter types that can be found in the **ui.json** format.

Boolean parameter

A parameter named “input” that has a `bool` value.

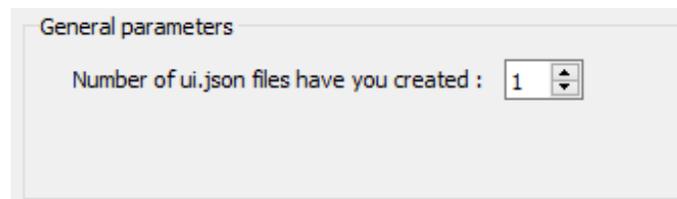

```
{
  "input":{
    "main": true,
    "label": "Do you like Python?",
    "value": true,
    "tooltip": "Check if you like Python"
  }
}
```

Integer parameter

A parameter that has an `int` value. The optional parameters `min` and `max` invoke a validator to insure the bound(s) are enforced.

```
{
  "file_xp":{
    "main": true,
    "label": "Number of ui.json files have you created",
    "value": 1,
    "min": 0,
    "max": 100
  }
}
```

Float parameter

A parameter that has a `float` value. The optional parameters are:

min float

Minimum value allowed for validator of the **value** member. The default is the minimum numeric limits of float.

max float

Maximum value allowed for validator of the **value** member. The default is the maximum numeric limits of float.

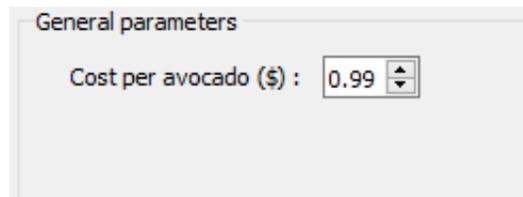

lineEdit bool

Boolean whether to use a line edit (**true**) or a spin box (**false**). The default is true.

precision int

Number of decimal places in the line edit or spin box

```
{
  "avacado": {
    "main": true,
    "label": "Cost per avacado ($)",
    "value": 0.99,
    "min": 0.29,
    "precision": 2,
    "lineEdit": false,
    "max": 2.79
  }
}
```

String parameter

For a simple string parameter, use an empty `str` value to have an empty string. Only a `label` and `value` is required.

```
{
  "my_string": {
    "main": true,
    "label": "Name",
    "value": "Default answer"
  }
}
```

Multi-choice string parameter

For a drop-down selection, add a `choiceList` member with an array of strings (`str`)

```
{
  "favourites":
  {
    "choiceList": ["Northwest Territories",
                  "Yukon",
                  "Nunavut"],
    "main": true,
    "label": "Favourite Canadian territory",
    "value": "Yukon"
  }
}
```

File parameter

A file parameter comes with an icon to choose the file, with a `str` value. Extra members of the file object parameter are **fileDescription** and **fileType**. Both of these are `str` types and can be arrays, but must be of the same length

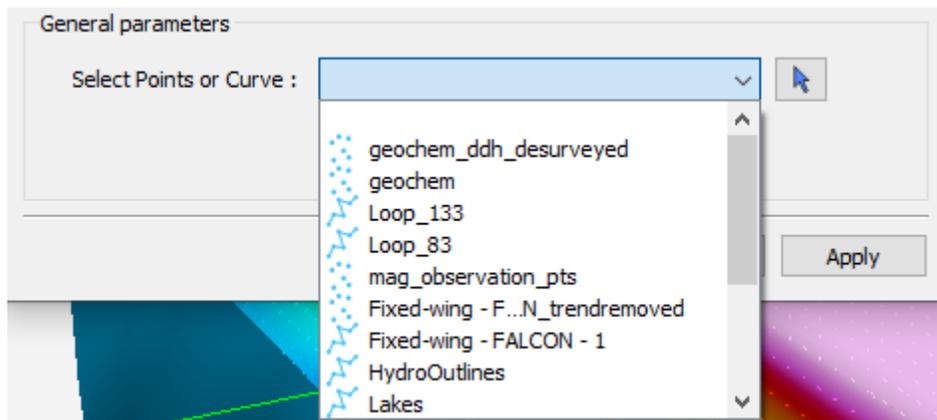

```
{
  "model_file": {
    "fileDescription": ["Chargeability", "Conductivity"],
    "fileType": ["chg", "con"],
    "main": true,
    "label": "DC/IP model file",
    "value": ""
  }
}
```

Geoscience ANALYST Object parameter

To choose an object from a dropdown menu, the **universally unique identifier (UUID)** of the *Object Type*: is required for the filtering of objects. This is given as a single or array of `str` in the member **meshType**. The icon to pick the object comes with this parameter. The value returned is the *UUID* of the Geoscience ANALYST object selected.

```
{
  "interesting_object": {
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,
      "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],
    "main": true,
    "label": "Select Points or Curve",
    "value": ""
  }
}
```

Geoscience ANALYST Data parameter

Creating a parameter to choose a Geoscience ANALYST object's data requires extra members:

dataType str

Describes the type of data to filter. One or more (as an array) of these key words: Integer, Float, Text, Referenced, Vector, DateTime, Geometric, Boolean, or Text.

association str

Describes the geometry of the data. One or more of these key words: Vertex, Cell, or Face.

parent str

Either a *UUID* of the parent or the name of the *Object parameter* JSON object to allow the user to choose the mesh.

isValue bool

Describes whether to read the **value** (float) or **property** (str) member. If not given, the value member is an *UUID* and is considered a *drop-down data parameter*. If this member is given along with **property**, then an icon is added to the UI element, which switches between the **value** (line edit) and **property** (drop-down) choices. This value is updated on export depending on the style choice (float or str)

property str.

Data *UUID* that is selected when **isValue** is present. Geoscience ANALYST Pro will update this value on export.

min float

Optional minimum value allowed for validator of the **value** member. The default is the minimum numeric limits of float.

max float

Optional maximum value allowed for validator of the **value** member. The default is the maximum numeric limits of float.

precision int

Optional number of decimal places for the value.

Drop-down data parameter

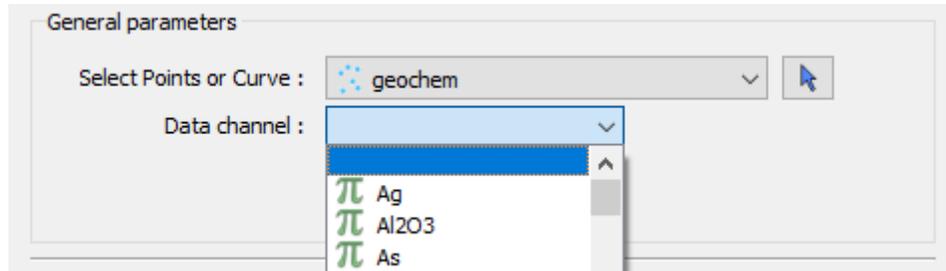

In this example, the object parameter *data_mesh* is also given for reference.

```
{
  "data_channel": {
    "main": true,
    "association": "Vertex",
    "dataType": "Float",
    "label": "Data channel",
    "parent": "data_mesh",
    "value": ""
  },
  "data_mesh": {
    "main": true,
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,
      "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],
    "main": true,
    "label": "Select Points or Curve",
  }
}
```

(continues on next page)

(continued from previous page)

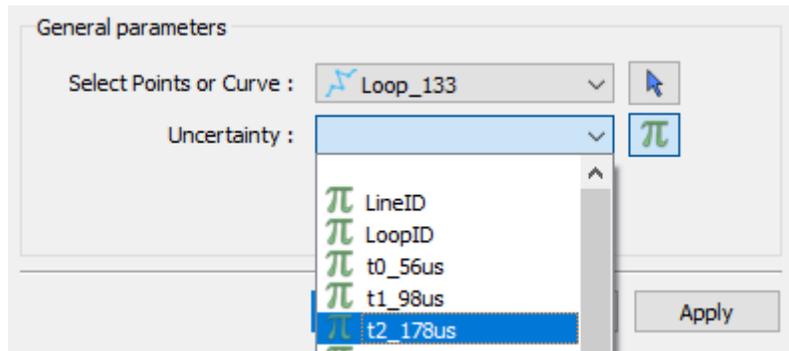

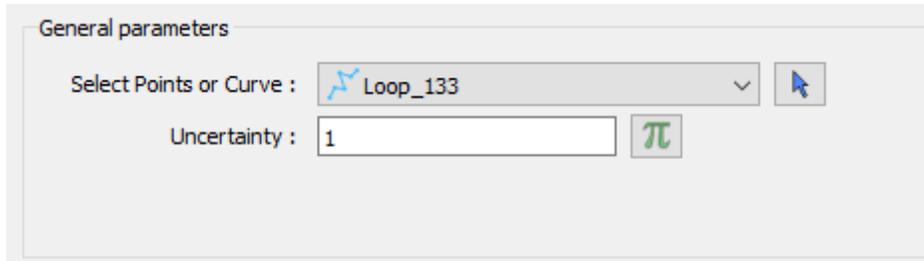

```
"value": ""
}
}
```

Data or value parameter

In some cases, a parameter may take its data from a Geoscience ANALYST object or simply a float value. The use of the member **isValue** and **property** together allows for the UI to switch between these two cases. In the top image, the **isValue** is true, so the **value** member of 1.0 will initially be active. When the icon is clicked, the type of input is switched to the **property** member (bottom image). The **uncertainty channel** object also depends on the **data_mesh** object. The drop-down selection will filter data from the chosen object that is located on the vertices and is float. The **isValue** is set to false upon export in this case.

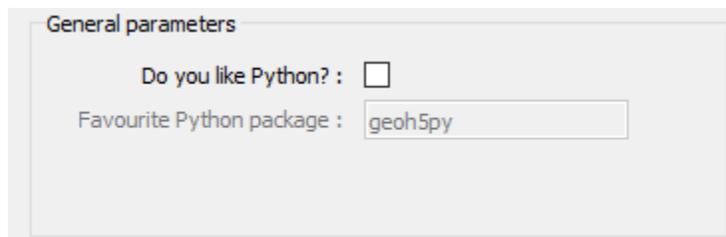

```
{
  "uncertainty_channel": {
    "main": true,
    "association": "Vertex",
    "dataType": "Float",
    "isValue": true,
    "property": "",
    "min": 0.001,
    "label": "Uncertainty",
    "parent": "data_mesh",
    "value": 1.0
  },
  "data_mesh": {
    "main": true,
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,
      "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],
    "main": true,
    "label": "Select Points or Curve",
    "value": ""
  }
}
```

Dependencies on other parameters

Use the **dependency** and **dependencyType** members to create dependencies. The parameter driving the dependency should set **optional** to true or be a *Boolean parameter*. Below are a couple of examples. The first initializes the *favourite_package* parameter as disabled until the *python_interest* parameter is checked. The second shows the opposite when the **enabled** member is set to true.

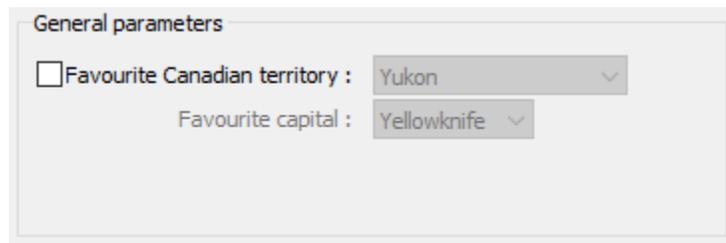

```
{
  "python_interest": {
    "main": true,
    "label": "Do you like Python?",
    "value": false,
    "tooltip": "Check if you like Python"
  },
  "favourite_package": {
    "main": true,
    "label": "Favourite Python package",
    "value": "geoh5py",
    "dependency": "python_interest",
    "dependencyType": "enabled"
  }
}
```

The next example has a dependency on an optional parameter. The **enabled** member is set to false so

that it is not automatically checked. The *city* and *territory* parameters will be enabled when the *territory* checkbox is checked.

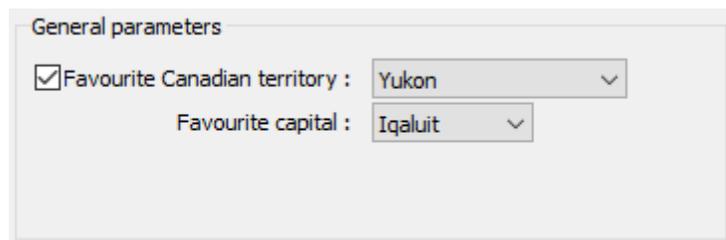

```
{
  "territory": {
    "choiceList": ["Northwest Territories",
                  "Yukon",
                  "Nunavut"],
    "main": true,
    "label": "Favourite Canadian territory",
    "value": "Yukon",
    "optional": true,
    "enabled": false
  },
  "city": {
    "main": true,
    "choiceList": ["Yellowknife",
                  "Whitehorse",
                  "Iqaluit"],
    "label": "Favourite capital",
    "value": "",
    "dependency": "territory",
    "dependencyType": "enabled"
  }
}
```

General parameters

Favourite Canadian territory : Yukon

Favourite capital : Yellowknife

General parameters

Favourite Canadian territory : Yukon

Favourite capital : Iqaluit

2.5.5 Exporting from Geoscience ANALYST

When a **ui.json** is saved with Geoscience ANALYST Pro, the following object members are updated or added:

- The **value** member with the appropriate type
- The **enabled** member `bool` for whether the parameter is enabled
- The *Data parameter* will also have updated **isValue** and **property** members. The **isValue** `bool` member is *true* if the **value** member was selected and *false* if the **property** member was selected.

The following JSON objects will be written (and overwritten if given) upon export from Geoscience ANALYST Pro:

- `monitoring_directory str` the absolute path of a monitoring directory. Workspace files written to this folder will be automatically processed by Geoscience ANALYST.
- `workspace_geoh5 str` the absolute path to the current workspace (if previously saved) being used
- `geoh5 str` the absolute path to the geoh5 written containing all the objects of the workspace within the parameters of the **ui.json**. One only needs to use this workspace along with the JSON file to access the objects with geoh5py.

2.5.6 Tips on creating UIs

Here are a few tips on creating good looking UIs:

- Keep labels short and concise. Be consistent with capitalization and do not include the colons. Geoscience ANALYST will add colons and align them.
- Write detailed tooltips.
- Group related objects, but do not use a group if there are fewer than 3 objects.
- The **main** member is for general, required parameters. Do not include this member with every object, unless there are only a handful of objects. Objects that are in the required parameters without a valid value will invoke an error when exporting or running from Geoscience ANALYST. “Non-main” members are designated to a second page under *Optional parameters*.
- Utilize **optional** object members and dependencies. If a single workspace object input is optional, use the *Object parameter* rather than two parameters with a dependency.

2.6 Release Notes

2.6.1 Release 0.3.0 - 2022/06/30

This release addresses changes introduced by the geoh5 v2.0 standard.

- Drillhole objects and associated data are stored as Concatenated entities under the DrillholeGroup.
- Use of context manager for the Workspace with options for read/write mode specifications added.
- Implementation of a SimPEGGroup entity.

2.6.2 Release 0.2.0 - 2022/04/18

- Add MT, tipper and airborne time-domain survey objects.
- Add ui.json read/write with validations
- Bug fixes and documentation.

2.6.3 Release 0.1.6 - 2021/12/09

- Fix StatsCache on value changes.
- Fix crash if data values are None.
- Clean up for linters

2.6.4 Release 0.1.5 - 2021/11/05

- Fix for copying of direct-current survey.
- Fix documentation.

2.6.5 Release 0.1.4 - 2021/08/31

- Add direct_current survey type and related documentation.
- Fix for drillholes with single survey location anywhere along the borehole.
- Fix for entity.parent setter. Changes are applied directly to the target workspace.
- Improve Typing.
