Welcome to the documentation page for **geoh5py**!

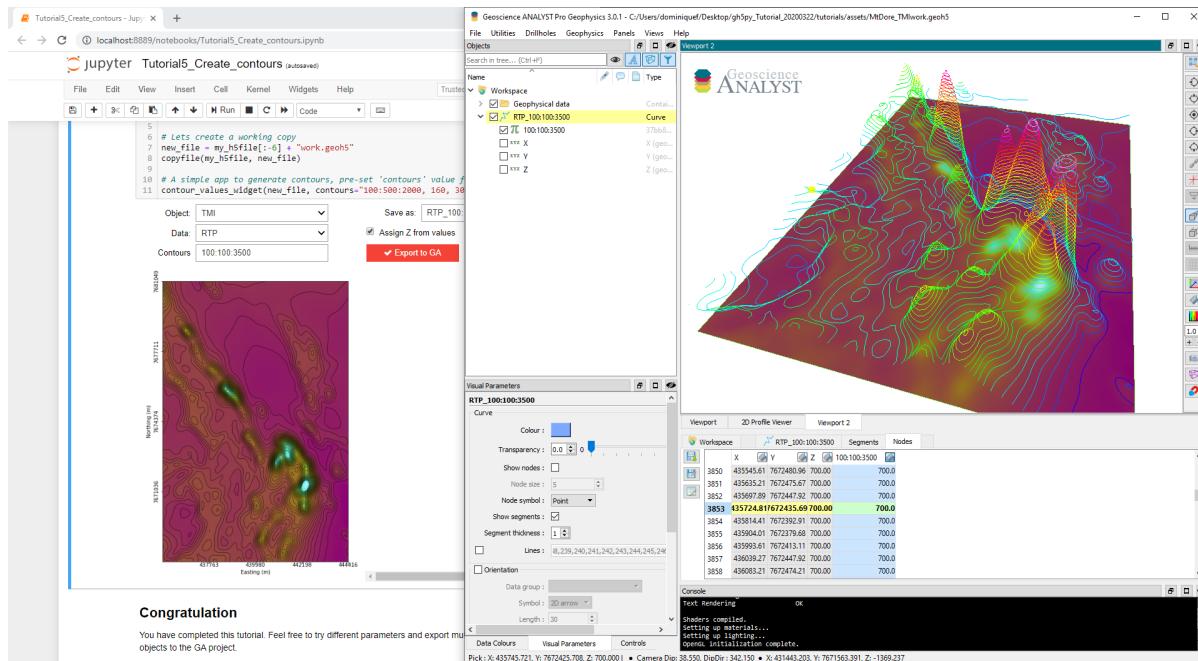

---

# CHAPTER ONE

---

## IN SHORT

The **geoh5py** library has been created for the manipulation and storage of a wide range of geoscientific data (points, curve, surface, 2D and 3D grids) in **geoh5** file format. Users will be able to directly leverage the powerful visualization capabilities of Geoscience ANALYST along with open-source code from the Python ecosystem.

## CONTENTS:

### 2.1 Installation

**geoh5py** is currently written for Python 3.7 or higher, and depends on [NumPy](#) and [h5py](#).

---

**Note:** Users will likely want to take advantage of other packages available in the Python ecosystem. We therefore recommend using [Anaconda](#) to manage the installation.

---

Install **geoh5py** from PyPI:

```
$ pip install geoh5py
```

To install the latest development version of **geoh5py**, you can use pip with the latest GitHub development branch:

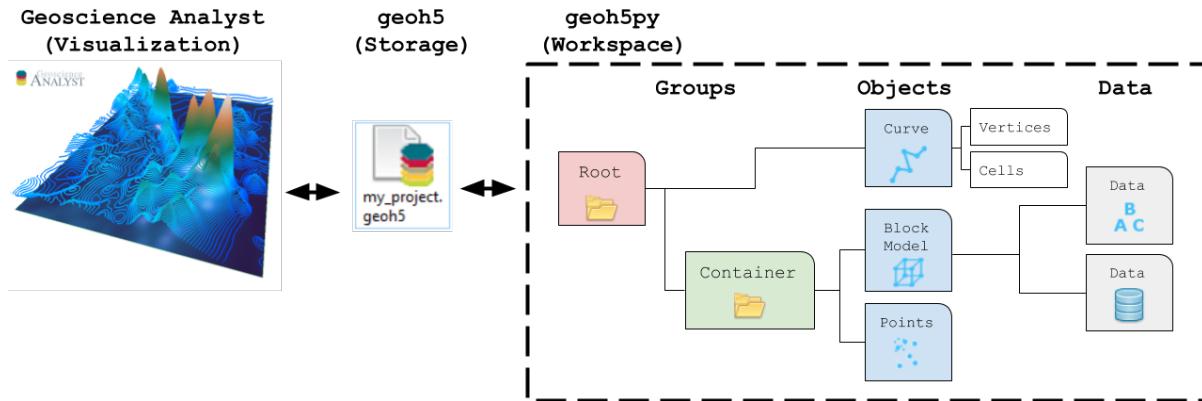

```
$ pip install git+https://github.com/MiraGeoscience/geoh5py.git
```

To work with **geoh5py** source code in development, install from GitHub:

```
$ git clone --recursive https://github.com/MiraGeoscience/geoh5py.git
$ cd geoh5py
$ python setup.py install
```

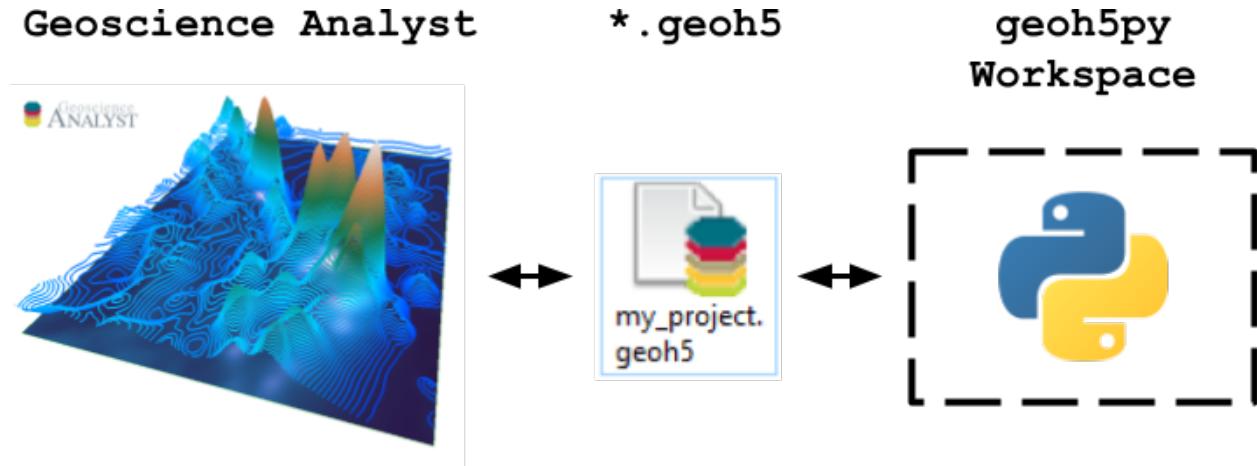

## 2.2 Tutorials

This section provides information on how to use the **geoh5py** package, from the creation of a *Workspace* to the creation and manipulation of *Entities*

### 2.2.1 Workspace

The core element of a project is the **Workspace**. A project Workspace holds core information about the author, version and all entities stored in the geoh5 file. It also knows how to create the core structure needed by **Geoscience ANALYST** for visualization.

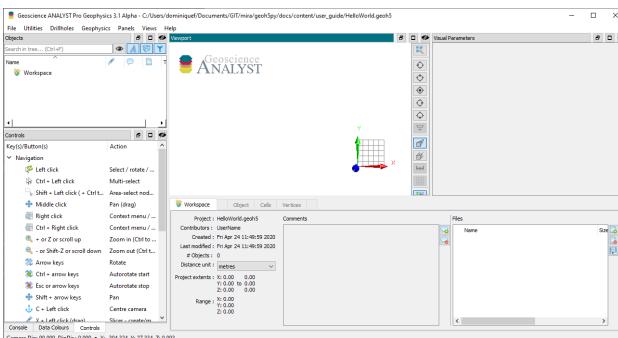

#### Open and close

You can either open an existing project or create a new project by simply entering the desired file name.

```
[1]: from geoh5py.workspace import Workspace

# Create a new project
workspace = Workspace("my_project.geoh5")
```

Et voila!

By default, the `*.geoh5` file is accessed in “read-write” mode. In the eventuality that the file is already used by Geoscience ANALYST, the mode gets changed to “read-only”. This prevents users from modifying the file while used in an active session, but still allows them to extract data from the workspace. The same restriction does not apply to multiple python processes, as permitted by the **Single Writer Multiple Reader** (SWMR) feature of HDF5.

```
[2]: print(workspace.geoh5)

<HDF5 file "my_project.geoh5" (mode r+)>
```

After completing the read/write process, the workspace must be closed in order to release the file. Geoscience ANALYST does not allow reading on an opened file.

```
[3]: workspace.close()

print(workspace._geoh5)

None
```

## Context manager

Likewise, a workspace can be accessed via a context manager which will handle closing the file at the end of a process.

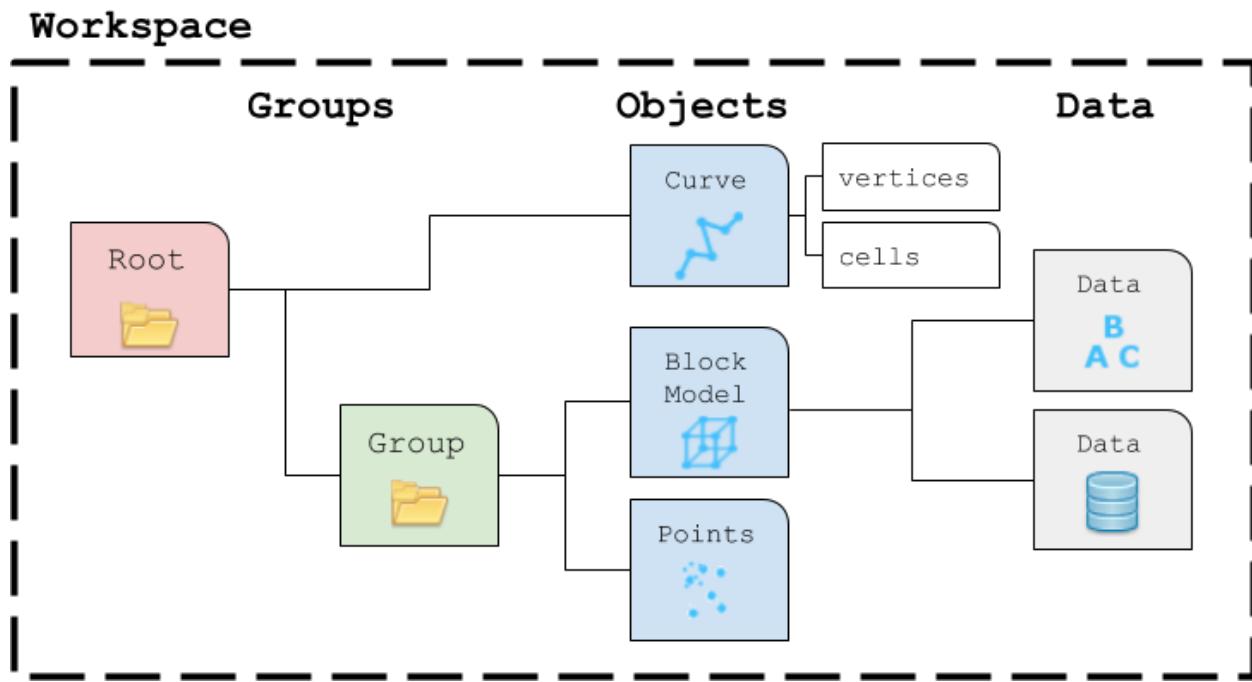

```
[4]: with Workspace("my_project.geoh5") as workspace:
    print(workspace.geoh5)

print(workspace._geoh5)

<HDF5 file "my_project.geoh5" (mode r+)>
None
```

## 2.2.2 Entities

This section introduces the different entities that can be created and stored in the geoh5 file format.

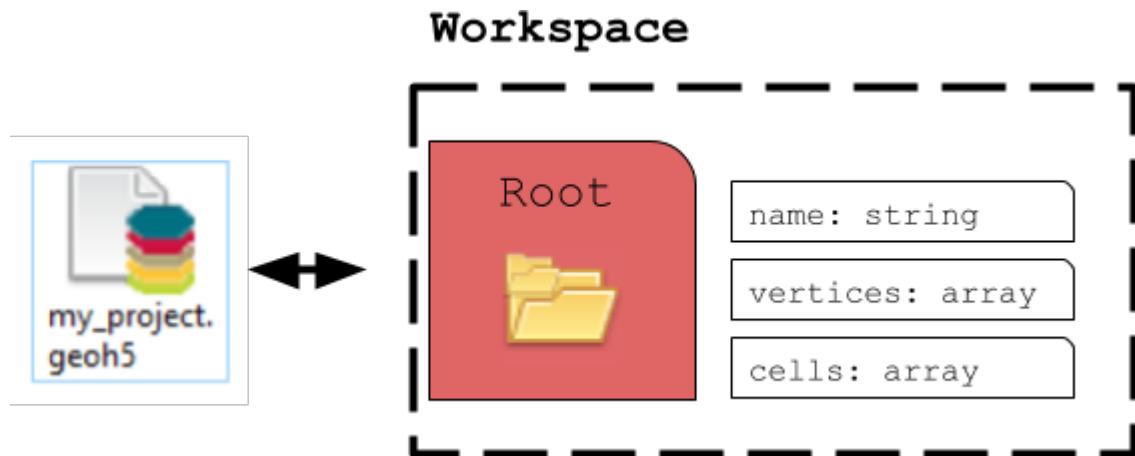

## Groups

Groups are effectively containers for other entities, such as Objects (Points, Curve, Surface, etc.) and other Groups. Groups are used to establish parent-child relationships and to store information about a collection of entities.

### RootGroup

By default, the parent of any new Entity is the workspace `RootGroup`. It is the only entity in the `Workspace` without a parent. Users rarely have to interact with the `Root` group as it is mainly used to maintain the overall project hierarchy.

## ContainerGroup

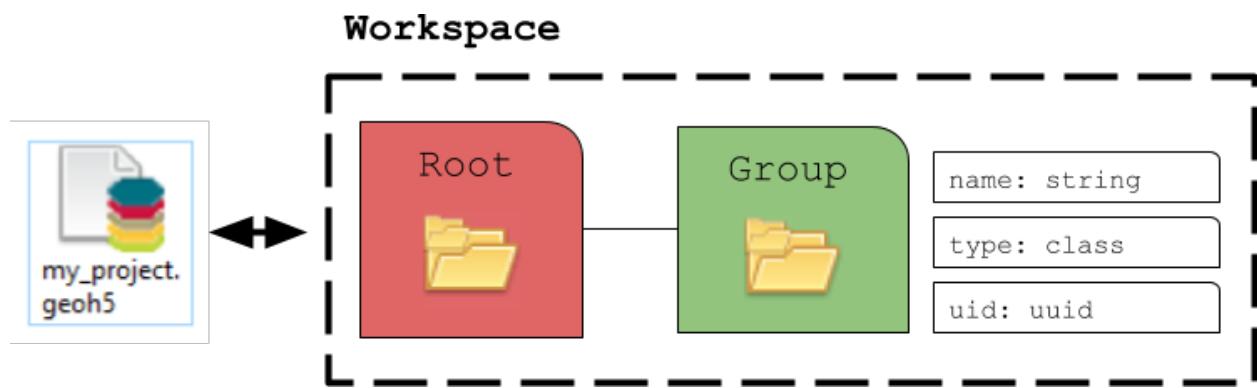

A ContainerGroup can easily be added to the workspace and can be assigned a name and description.

```
[1]: from geoh5py.groups import ContainerGroup
from geoh5py.workspace import Workspace
import numpy as np

# Create a blank project
workspace = Workspace("my_project.geoh5")

# Add a group
group = ContainerGroup.create(workspace, name='myGroup')
```

At creation, "myGroup" is written to the project geoh5 file and visible in the Analyst project tree.

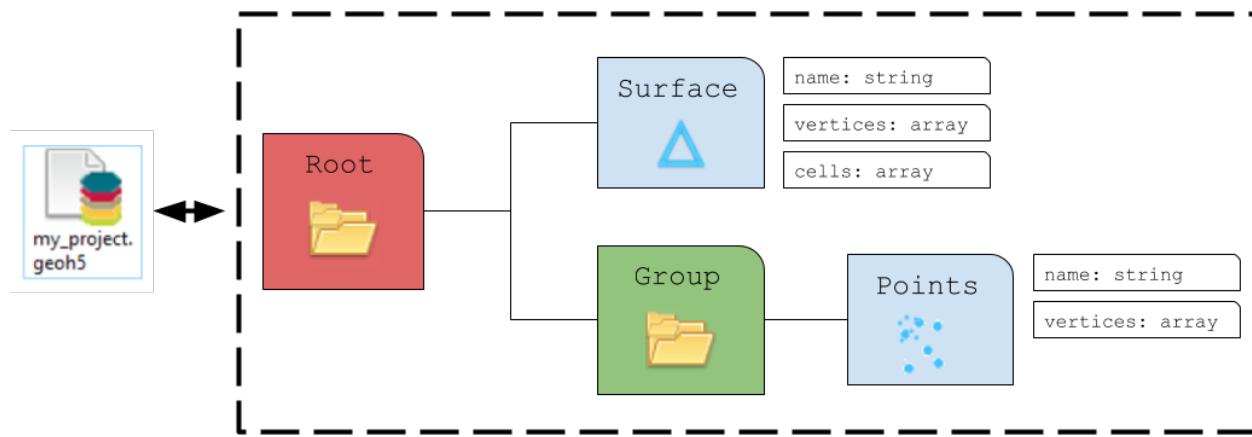

Any entity can be accessed by its name or uid (unique identifier):

```
[2]: print(group.uid)
print(workspace.get_entity("myGroup")[0] == workspace.get_entity(group.uid)[0])
608fc1c-90ce-489d-b7b6-baeeefc6a749
True
```

## Objects

The geoh5 format enables storing a wide variety of Object entities that can be displayed in 3D. This section describes the collection of Objects entities currently supported by geoh5py.

## Points

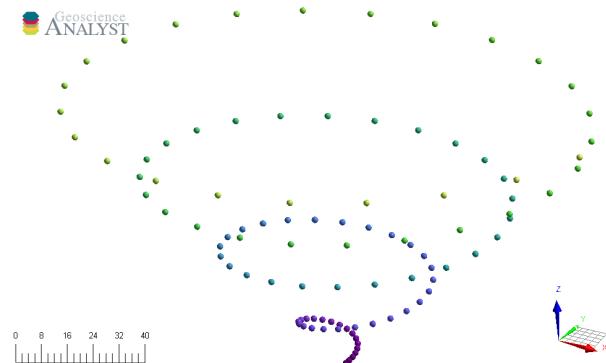

The Points object consists of a list of vertices that define the location of actual data in 3D space. As for all other Objects, it can be created from an array of 3D coordinates and added to any group as follow:

```
[3]: from geoh5py.objects import Points

# Generate a numpy array of xyz locations
n = 100
radius, theta = np.arange(n), np.linspace(0, np.pi*8, n)

x, y = radius * np.cos(theta), radius * np.sin(theta)
z = (x**2. + y**2.)**0.5
xyz = np.c_[x.ravel(), y.ravel(), z.ravel()] # Form a 2D array

# Create the Point object
points = Points.create(
    workspace,          # The target Workspace
    vertices=xyz       # Set vertices
)
```

## Curve

The Curve object, also known as a polyline, is often used to define contours, survey lines or geological contacts. It is a sub-class of the Points object with the added `cells` property, that defines the line segments connecting its `vertices`. By default, all vertices are connected sequentially following the order of the input vertices.

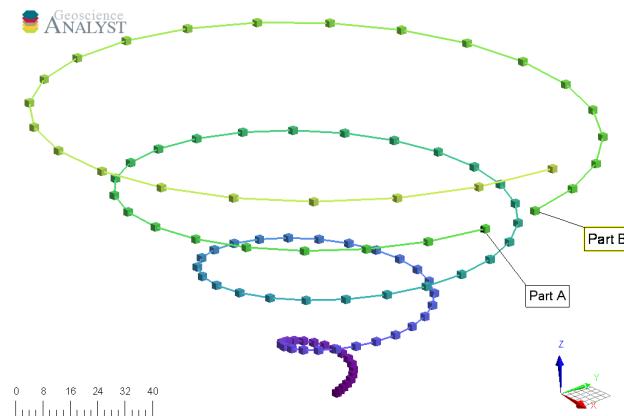

```
[4]: from geoh5py.objects import Curve

# Create the Curve object
curve = Curve.create(
    workspace,          # The target Workspace
    vertices=xyz
)
```

Alternatively, the `cells` property can be modified, either directly or by assigning `parts` identification to each `vertices`:

```
[5]: # Split the curve into two parts
part_id = np.ones(n, dtype="int32")
part_id[:75] = 2

# Assign the part
curve.parts = part_id
```

## Drillhole

Drillhole objects are different from other objects as their 3D geometry is defined by the `collar` and `surveys` attributes. As for version geoh5 v2.0, the drillholes require a DrillholeGroup entity to store the geometry and data.

```
[6]: from geoh5py.groups import DrillholeGroup
from geoh5py.objects import Drillhole

dh_group = DrillholeGroup.create(workspace)

# Create a simple well
total_depth = 100
dist = np.linspace(0, total_depth, 10)
```

(continues on next page)

(continued from previous page)

```

azm = np.ones_like(dist) * 45.
dip = np.linspace(-89, -75, dist.shape[0])
collar = np.r_[0., 10., 10]

well = Drillhole.create(
    workspace, collar=collar, surveys=np.c_[dist, azm, dip], name="Drillhole", parent=dh_
    ↪group
)

print(well.name)

```

Drillhole

## Surface

The Surface object is also described by vertices and cells that form a net of triangles. If omitted on creation, the cells property is calculated using a 2D `scipy.spatial.Delaunay` triangulation.

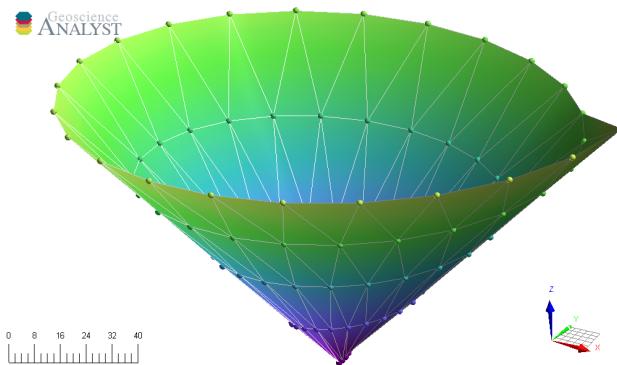

```

[7]: from geoh5py.objects import Surface
from scipy.spatial import Delaunay

# Create a triangulated surface from points
surf_2D = Delaunay(xyz[:, :2])

# Create the Surface object
surface = Surface.create(
    workspace,
    vertices=points.vertices, # Add vertices
    cells=surf_2D.simplices
)

```

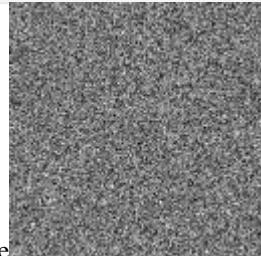

## GeoImage

The GeoImage object handles raster data, either single or 3-band images.

```
[8]: from geoh5py.objects import GeoImage
geoimage = GeoImage.create(workspace)
```

Image values can be assigned to the object from either a 2D `numpy.ndarray` for single band (gray):

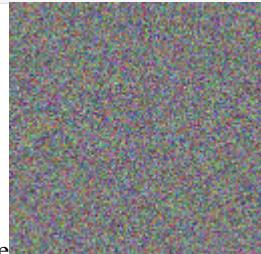

```
[9]: geoimage.image = np.random.randn(128, 128)
display(geoimage.image)
```

nbsphinx-code-borderwhite

or as 3D `numpy.ndarray` for 3-band RGB image:

```
[10]: geoimage.image = np.random.randn(128, 128, 3)
display(geoimage.image)
```

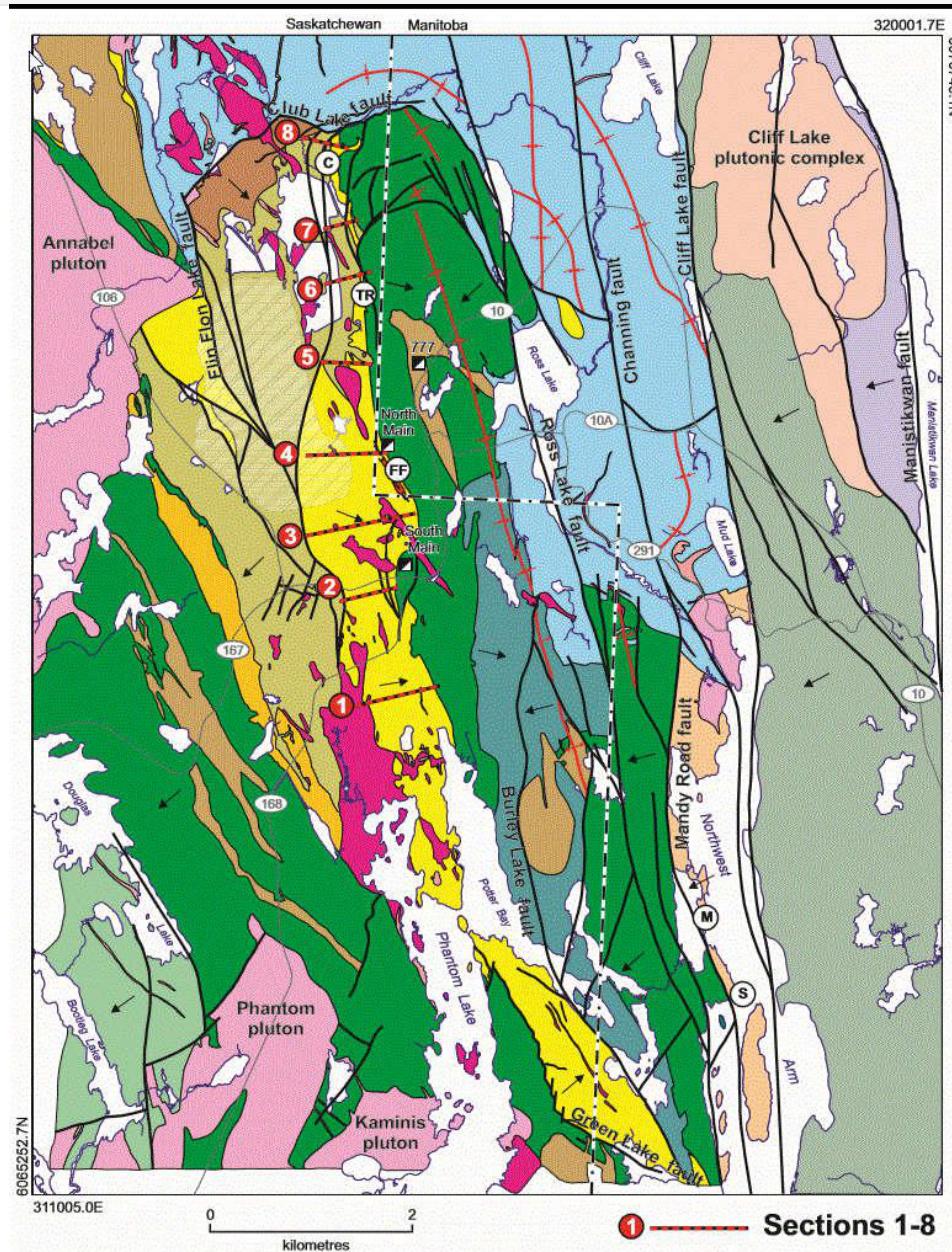

nbsphinx-code-borderwhite

or directly from file (png, jpeg, tiff).

```
[11]: geoimage.image = "./images/flin_flin_geology.jpg"
```

A `PIL.Image` object gets exposed to the user, which can be used for common raster manipulation (rotation, filtering, etc). The modified raster is stored back on file as a blob (bytes).

[12]: `display(geoimage.image)`

nbsphinx-code-borderwhite **Figure 4.** Geology and structure of the Flin Flon District showing the location of stops and transects (modified after Simard et al., 2010).

## Geo-referencing

By default, the `GeoImage` object will be displayed at the origin (xy-plane) with dimensions equal to the pixel count. The utility function `GeoImage.georeference` lets users geo-reference the image in 3D space based on at least three (3) input reference points (pixels) with associated world coordinates.

[13]: `pixels = [  
 [18, 73],  
 [757, 1014],`

(continues on next page)

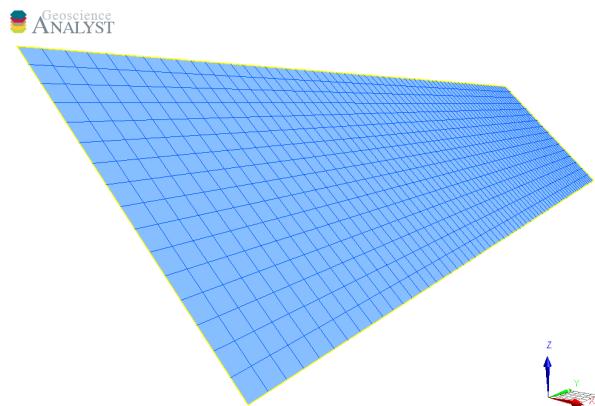

(continued from previous page)

```
[18, 1014],  
]  
coords = [  
    [311005, 6065252, 0],  
    [320001, 6076748, 0],  
    [311005, 6076748, 0]  
]  
  
geoimage.georeference(pixels, coords)  
print(geoimage.vertices)  
[[ 310785.88227334 6077065.63655685 0. ]  
 [ 320232.29093369 6077065.63655686 0. ]  
 [ 320232.29093369 6064360.17428268 0. ]  
 [ 310785.88227334 6064360.17428268 0. ]]
```

## Grid2D

The Grid2D object defines a regular grid of cells often used to display model sections or to compute data derivatives. A Grid2D can be oriented in 3D space using the origin, rotation and dip parameters.

```
[14]: from geoh5py.objects import Grid2D  
  
# Create the Surface object  
grid = Grid2D.create(  
    workspace,  
    origin = [25, -75, 50],  
    u_cell_size = 2.5,  
    v_cell_size = 2.5,  
    u_count = 64,  
    v_count = 16,  
    rotation = 90.0,  
    dip = 45.0,  
)
```

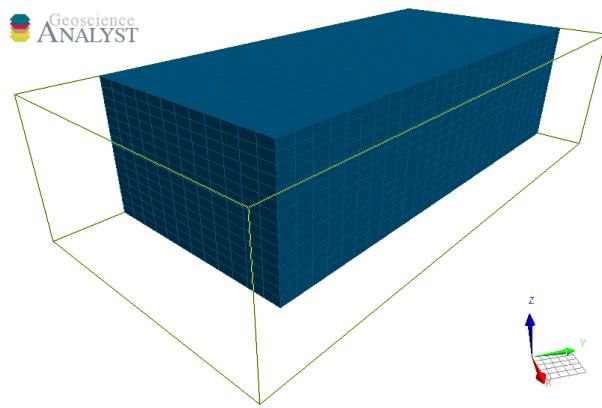

## BlockModel

The `BlockModel` object defines a rectilinear grid of cells, also known as a tensor mesh. The `cells` center position is determined by `cell_delimiters` (offsets) along perpendicular axes (`u`, `v`, `z`) and relative to the `origin`. `BlockModel` can be oriented horizontally by controlling the `rotation` parameter.

```
[15]: from geoh5py.objects import BlockModel

# Create the Surface object
blockmodel = BlockModel.create(
    workspace,
    origin = [25, -100, 50],
    u_cell_delimiters=np.cumsum(np.ones(16) * 5), # Offsets along u
    v_cell_delimiters=np.cumsum(np.ones(32) * 5), # Offsets along v
    z_cell_delimiters=np.cumsum(np.ones(16) * -2.5), # Offsets along z (down)
    rotation = 30.0
)
```

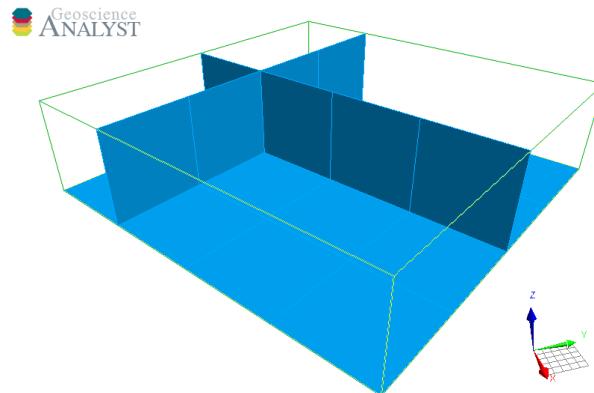

## Octree

The `Octree` object is type of 3D grid that uses a tree structure to define `cells`. Each cell can be subdivided it into eight octants allowing for a more efficient local refinement of the mesh. The `Octree` object can also be oriented horizontally by controlling the `rotation` parameter.

```
[16]: from geoh5py.objects import Octree

octree = Octree.create(
    workspace,
    origin=[25, -100, 50],
    u_count=16,      # Number of cells in power 2
    v_count=32,
    w_count=16,
    u_cell_size=5.0, # Base cell size (highest octree level)
    v_cell_size=5.0,
    w_cell_size=2.5, # Offsets along z (down)
    rotation=30,
)
```

By default, the octree mesh will be refined at the lowest level possible along each axes.

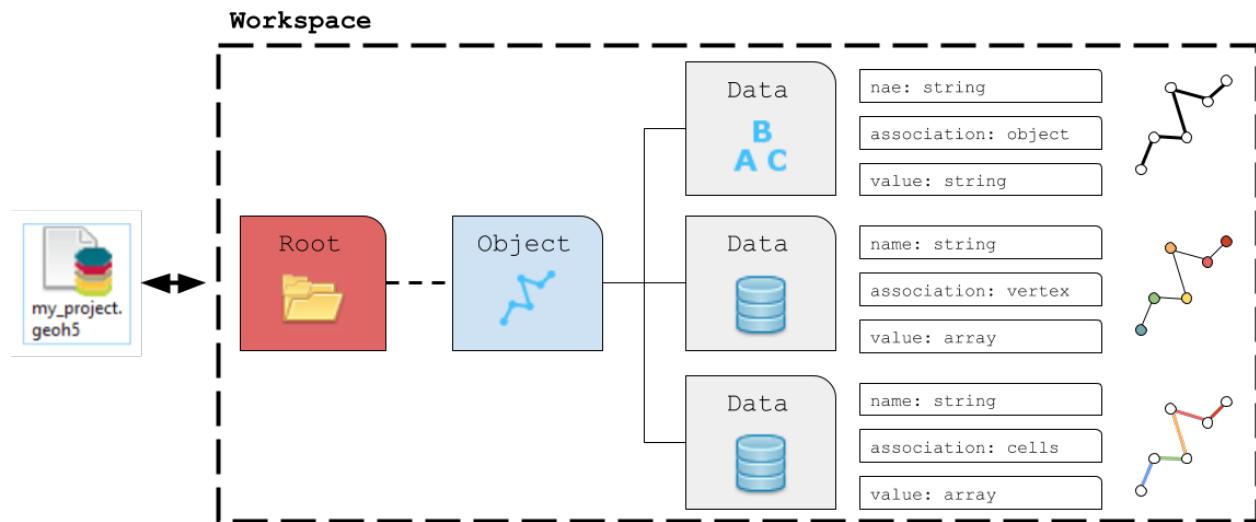

[17]: `workspace.close()`

### 2.2.3 Data

The geoh5 format allows storing data (values) on different parts of an Object. The data types currently supported by geoh5py are

- Float
- Integer
- Text
- Colormap
- Well log

```
[1]: from geoh5py.workspace import Workspace
import numpy as np

# Re-use the previous workspace
workspace = Workspace("my_project.geoh5")
```

(continues on next page)

(continued from previous page)

```
# Get the curve from previous section
curve = workspace.get_entity("Curve")[0]
```

## Float

Numerical `float` data can be attached to the various elements making up object. Data can be added to an `Object` entity using the `add_data` method.

```
[2]: curve.add_data({
    "my_cell_values": {
        "association": "CELL",
        "values": np.random.randn(curve.n_cells)
    }
})
[2]: <geoh5py.data.float_data.FloatData at 0x7fd28c9b70d0>
```

The association can be one of:

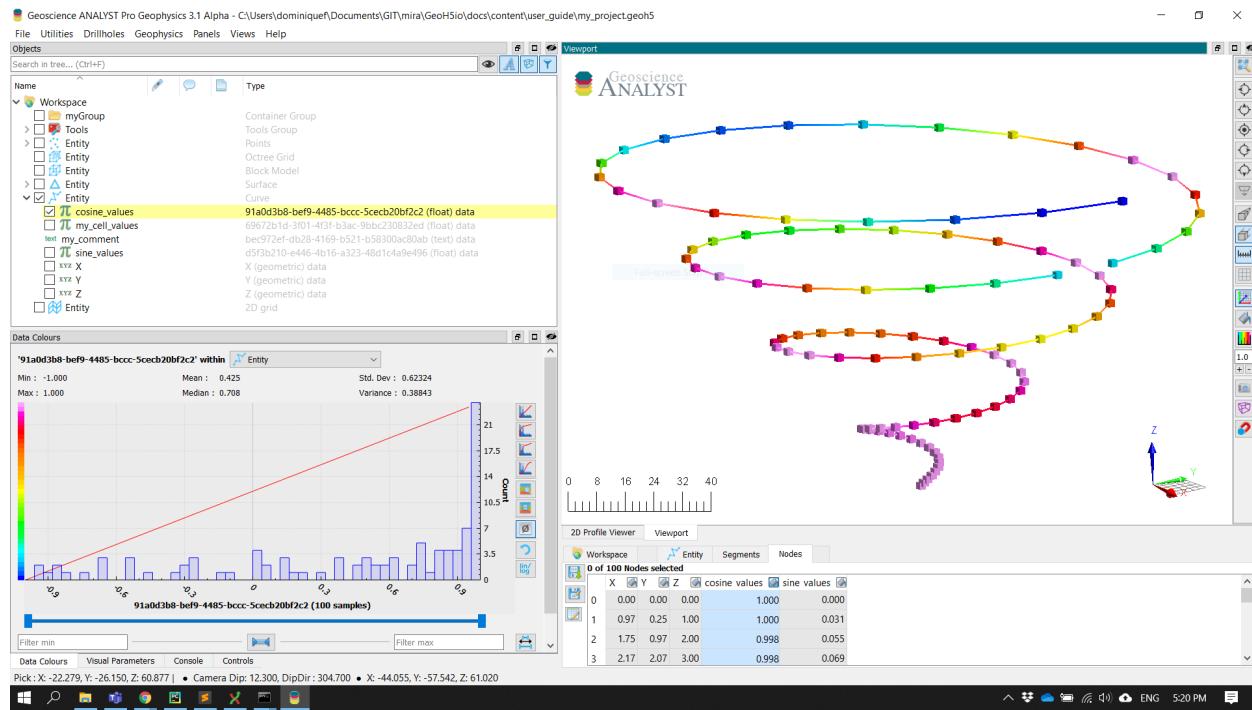

- OBJECT: Single element characterizing the parent object
- VERTEX: Array of values associated with the parent object vertices
- CELL: Array of values associated with the parent object cells

The length and order of the array of values must be consistent with the corresponding element of `association`. If the `association` argument is omitted, `geoh5py` will attempt to assign the data to the correct part based on the shape of the data values, either `object.n_values` or `object.n_cells`

```
[3]: # Add multiple data vectors on a single call
data = []
for ii in range(8):
    data[f"Period:{ii}"] = {
        "association": "VERTEX",
        "values": (ii+1) * np.cos(ii*curve.vertices[:, 0]*np.pi/curve.vertices[:, 0].
        ↪max() / 4.)
    }

data_list = curve.add_data(data)
print([obj.name for obj in data_list])
['Period:0', 'Period:1', 'Period:2', 'Period:3', 'Period:4', 'Period:5', 'Period:6',
 ↪'Period:7']
```

The newly created data is directly added to the project's `geoh5` file and available for visualization:

## Integer

Same implementation as for [Float](#) data type but with values provided as integer (int32).

## Text

Text (string) data can only be associated to the object itself.

```
[4]: curve.add_data({
    "my_comment": {
        "association": "OBJECT",
        "values": "hello_world"
    }
})
[4]: <geoh5py.data.text_data.TextData at 0x7fd28c818490>
```

## Colormap

The colormap data type can be used to store or customize the color palette used by Geoscience ANALYST.

```
[5]: from geoh5py.data.color_map import ColorMap

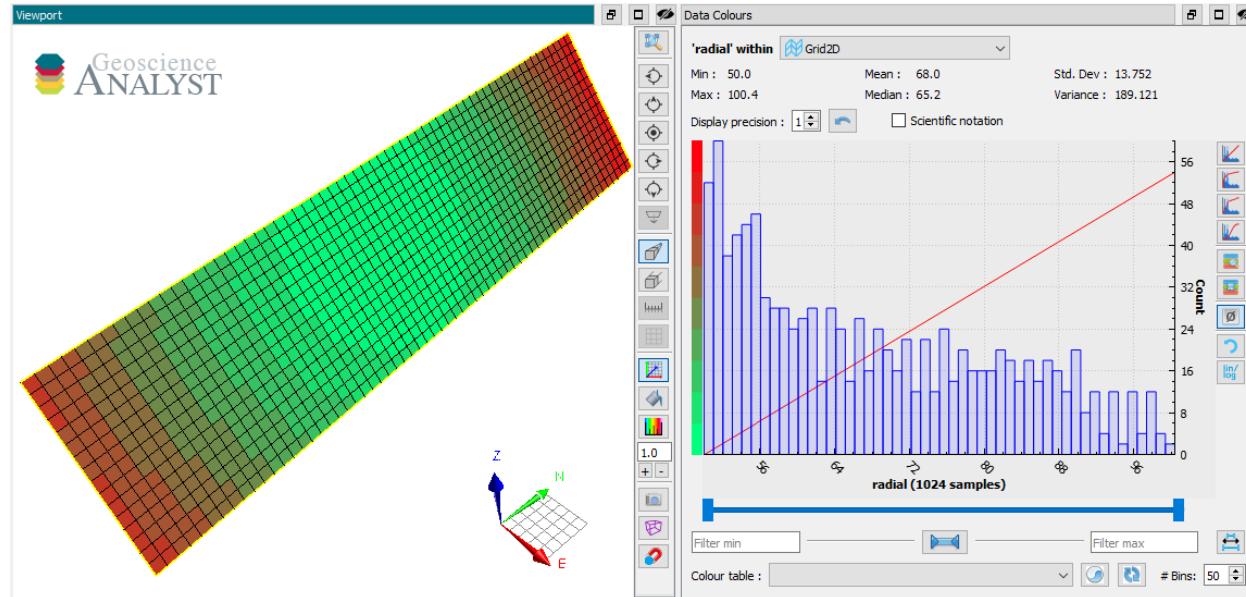

# Create some data on a grid2D entity.
grid = workspace.get_entity("Grid2D")[0]

# Add data
radius = grid.add_data({}
```

(continues on next page)

(continued from previous page)

```
"radial": {"values": np.linalg.norm(grid.centroids, axis=1)}
```

```
[6]: # Create a simple colormap that spans the data range
nc = 10
rgba = np.vstack([
    np.linspace(radius.values.min(), radius.values.max(), nc), # Values
    np.linspace(0, 255, nc), # Red
    np.linspace(255, 0, nc), # Green
    np.linspace(125, 15, nc), # Blue,
    np.ones(nc) * 255, # Alpha,
]).T
```

We now have an array that contains a range of integer values for red, green, blue and alpha (RGBA) over the span of the data values. This array can be used to implicitly create a [ColorMap](#) from the [EntityType](#).

```
[7]: # Assign the colormap to the data type
radius.entity_type.color_map = rgba
```

The resulting ColorMap stores the values to geoh5 as a `numpy.recarray` with fields for Value, Red, Green, Blue and Alpha.

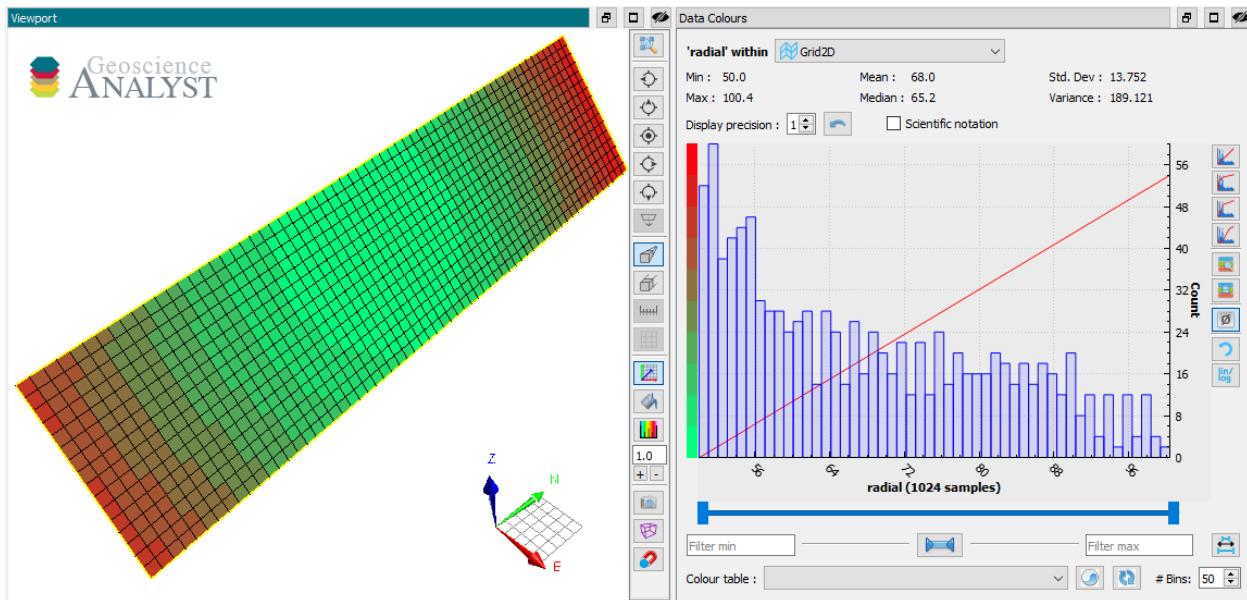

```
[8]: radius.entity_type.color_map._values
```

```
[8]: rec.array([( 50.03124024,    0, 255, 125, 255),
              ( 55.62664299,   28, 226, 112, 255),
              ( 61.22204575,   56, 198, 100, 255),
              ( 66.8174485 ,   85, 170,  88, 255),
              ( 72.41285126,  113, 141,  76, 255),
              ( 78.00825401,  141, 113,  63, 255),
              ( 83.60365676,  170,  85,  51, 255),
              ( 89.19905952,  198,  56,  39, 255),
              ( 94.79446227,  226,  28,  27, 255),
```

(continues on next page)

(continued from previous page)

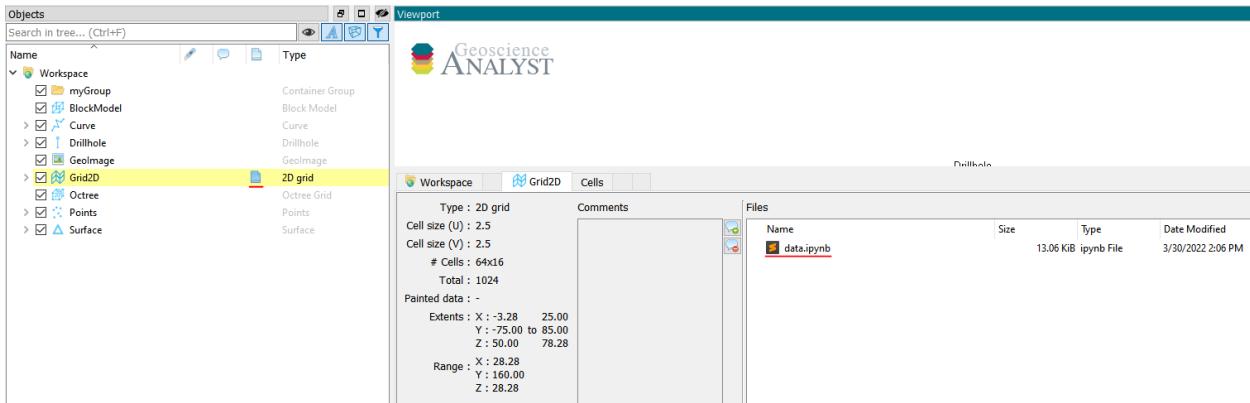

```
(100.38986503, 255, 0, 15, 255)],  
dtype=[('Value', '<f8'), ('Red', 'u1'), ('Green', 'u1'), ('Blue', 'u1'), (  
'Alpha', 'u1')])
```

## Files

Raw files can be added to groups and objects and stored as blob (bytes) data in geoh5.

```
[9]: file_data = grid.add_file("./data.ipynb")
```

The information can easily be re-exported out to disk with the `save` method.

```
[10]: file_data.save_file(path='./temp', name="new_name.ipynb")
```

## Well Data

In the case of `Drillhole` objects, data are always stored as from-to interval values.

## Depth Data

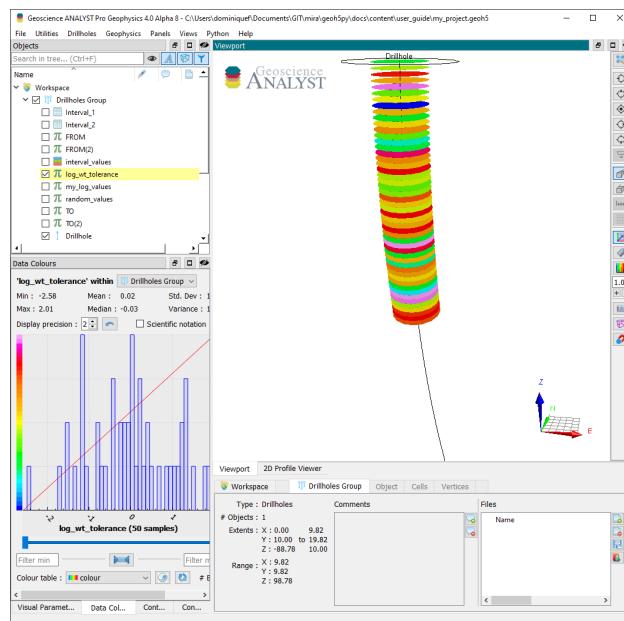

Depth data are used to represent measurements recorded at discrete depths along the well path. A depth attribute is required on creation. Depth markers are converted internally to from-to intervals by adding a small depth values defined by the `collocation_distance`. If the `Drillhole` object already holds depth data at the same location, `geoh5py` will group the datasets under the same `PropertyGroup`.

```
[12]: well = workspace.get_entity("Drillhole")[0]
depths_A = np.arange(0, 50.) # First list of depth

# Second list slightly offsetted on the first few depths
depths_B = np.arange(0.01, 50.01)

# Add both set of log data with 0.5 m tolerance
well.add_data({
    "my_log_values": {
        "depth": depths_A,
        "values": np.random.randn(depths_A.shape[0]),
    },
    "log_bt_tolerance": {
        "depth": depths_B,
        "values": np.random.randn(depths_B.shape[0]),
    }
})
```

[12]: [<abc.FloatDataConcatenated at 0x7fd289f92d10>, <abc.FloatDataConcatenated at 0x7fd289f92e50>]

## Interval (From-To) Data

Interval data are defined by constant values bounded by a start (FROM) and an end (TO) depth. A `from-to` attribute defined as a `numpy.ndarray` (nD, 2) is expected on creation. Subsequent data are appended to the same interval PropertyGroup if the `from-to` values match within the collocation distance parameter. Users can control the tolerance for matching intervals by supplying a `collocation_distance` argument in meters, or by setting the default on the drillhole entity (`default_collocation_distance = 1e-2` meters).

```
[13]: # Define a from-to array
from_to = np.vstack([
    [0.25, 25.5],
    [30.1, 55.5],
    [56.5, 80.2]
])

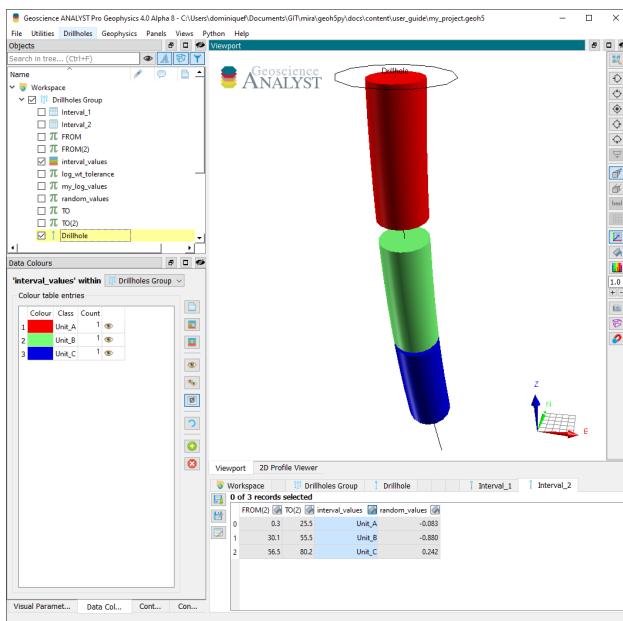

# Add some reference data
well.add_data({
    "interval_values": {
        "values": np.asarray([1, 2, 3]),
        "from-to": from_to,
        "value_map": {
            1: "Unit_A",
            2: "Unit_B",
            3: "Unit_C"
        },
        "type": "referenced",
    }
})

# Add float data on the same intervals
well.add_data({
    "random_values": {
        "values": np.random.randn(from_to.shape[0]),
        "from-to": from_to,
    }
})

/home/docs/checkouts/readthedocs.org/user_builds/geoh5py/conda/v0.4.0/lib/python3.7/site-
└─ packages/geoh5py/data/integer_data.py:66: UserWarning: Values provided in int64 are

  f"Values provided in {values.dtype} are converted to int32 for "

```

[13]: <abc.FloatDataConcatenated at 0x7fd289f92b90>

## Get data

Just like any `Entity`, data can be retrieved from the `Workspace` using the `get_entity` method. For convenience, `Objects` also have a `get_data_list` and `get_data` method that focusses only on their respective children `Data`.

```
[14]: my_list = curve.get_data_list()
print(my_list, curve.get_data(my_list[0]))
```

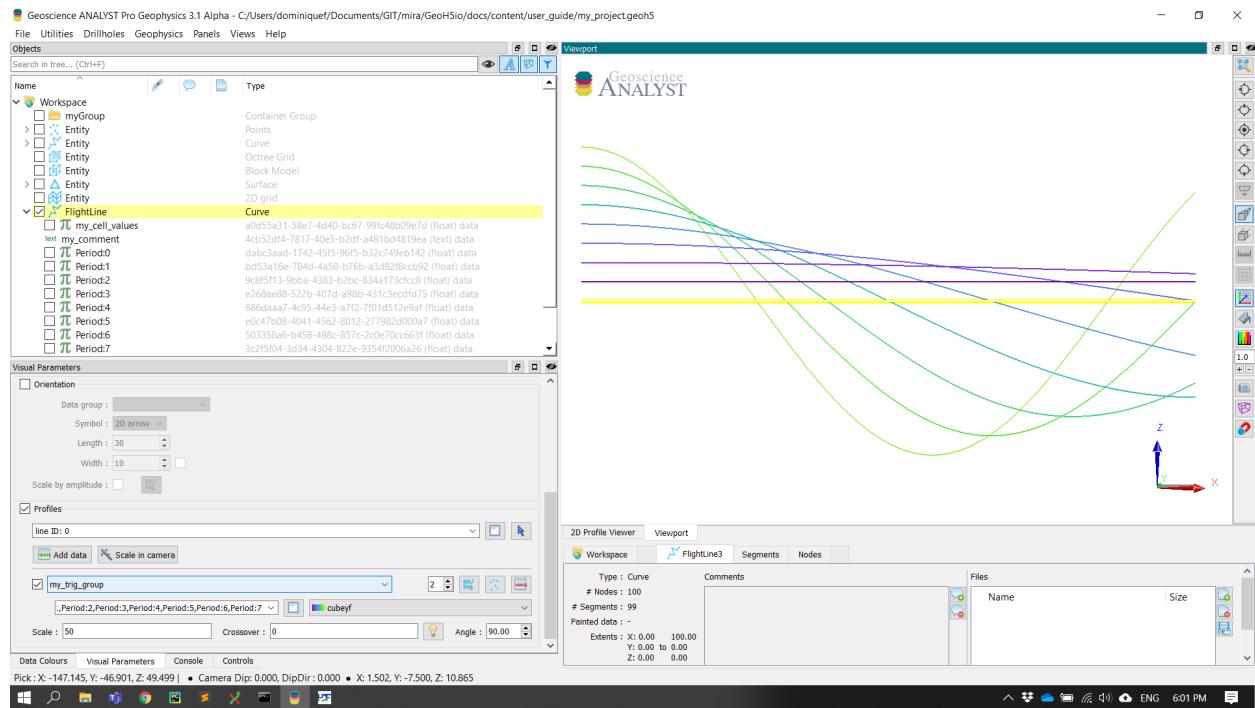

```
['Period:0', 'Period:1', 'Period:2', 'Period:3', 'Period:4', 'Period:5', 'Period:6',
 'Period:7', 'my_cell_values', 'my_comment'] [<geoh5py.data.float_data.FloatData object at 0x7fd2b8118510>]
```

## 2.2.4 Property Groups

Data entities sharing the same parent `Object` and association can be linked within a `property_groups` and made available through profiling. This can be used to group data that would normally be stored as 2D array.

```
[15]: # Add another VERTEX data and create a group with previous
curve.add_data_to_group([obj.name for obj in data_list], "my_trig_group")
```

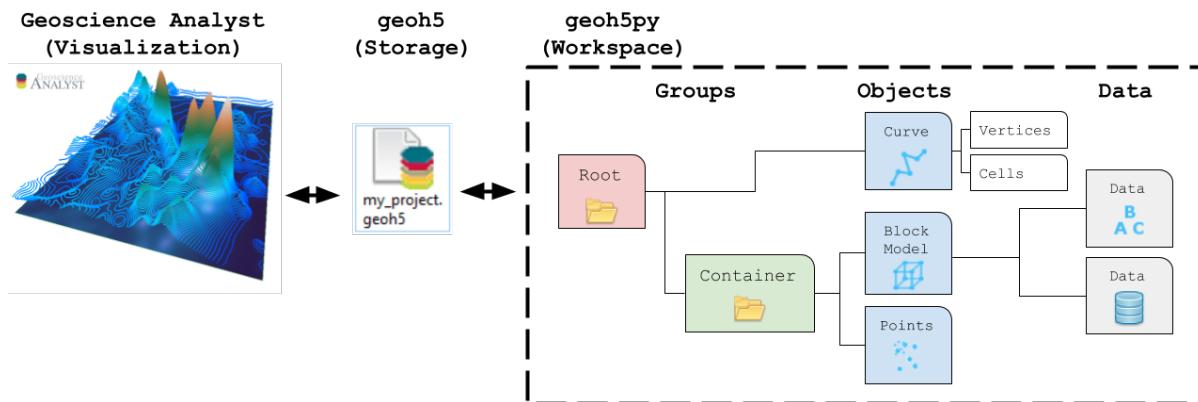

```
[15]: <geoh5py.groups.property_group.PropertyGroup at 0x7fd289f97a90>
```

[16]: `workspace.close()`

## 2.2.5 Surveys

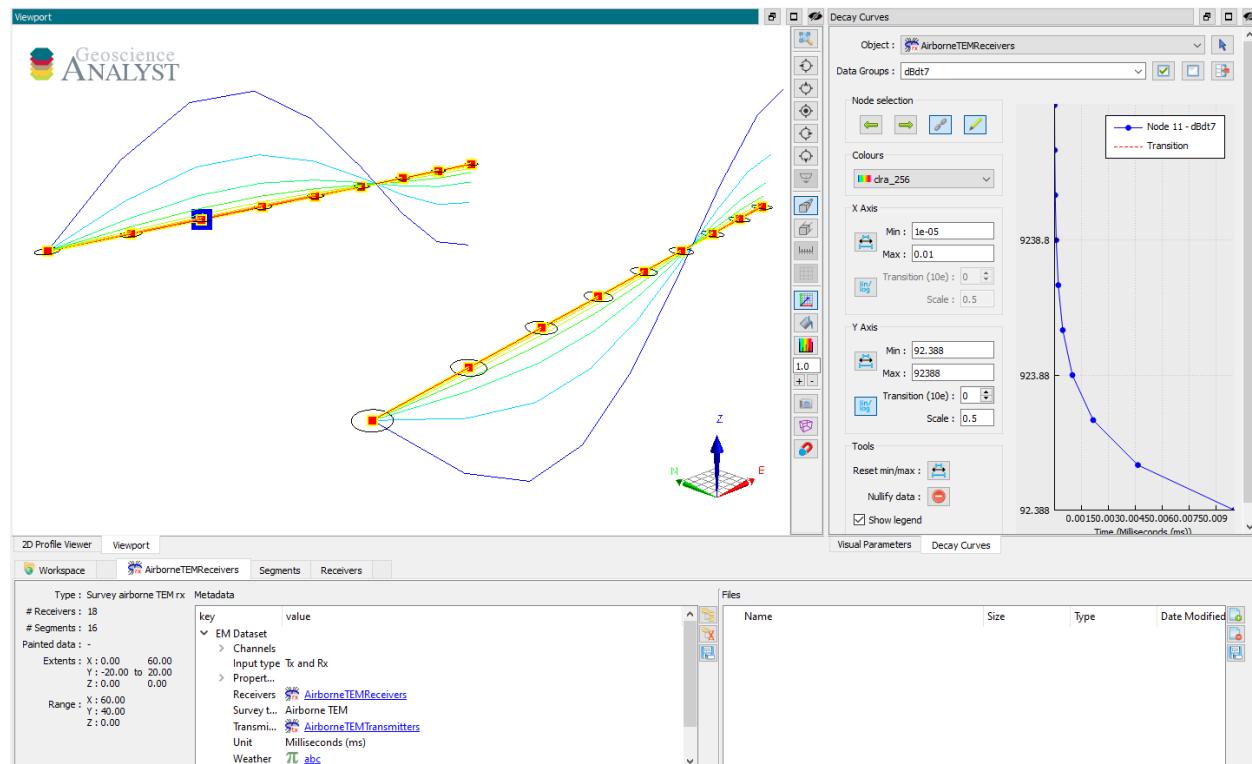

This section provides information on how to create geophysical surveys programmatically.

## Airborne Time-Domain

This type of survey can be used to store airborne time-domain electromagnetic (ATEM) data defined by a fixed transmitter-receiver loop configuration. The survey is made up of two entities ([AirborneTEMTransmitters](#) and [AirborneTEMReceivers](#)) linked by their metadata.

The following example shows how to generate an airborne TEM survey with associated data stored in geoh5 format and accessible from [Geoscience ANALYST](#).

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import AirborneTEMReceivers, AirborneTEMTransmitters

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_stations = 9
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_stations), np.linspace(-20, 20, n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_stations)).astype('int')

# Create the survey as a coincident loop system
aem_receivers = AirborneTEMReceivers.create(workspace, vertices=vertices, parts=parts)
aem_transmitters = AirborneTEMTransmitters.create(workspace, vertices=vertices,
```

(continues on next page)

(continued from previous page)

```
→parts=parts)
```

We have so far created two separate entities, one for transmitter locations and another for the receivers. In order to finalize the survey, the association must be made between the two entities:

[2]: `aem_receivers.transmitters = aem_transmitters`

or equivalently

[3]: `aem_transmitters.receivers = aem_receivers`

Only one of the two options above is needed.

Once linked, the two entities will share changes applied to the metadata. For example, changing the `input_type` property on the transmitters yield:

[4]: `aem_transmitters.input_type = "Tx and Rx"`  
`print(aem_receivers.input_type)`

Tx and Rx

## Metadata

Along with the survey object itself, the metadata contains all the necessary information to define the geophysical experiment.

[5]: `aem_receivers.metadata`

[5]: `{'EM Dataset': {'Channels': [],  
 'Input type': 'Tx and Rx',  
 'Property groups': [],  
 'Receivers': UUID('c1e8b90a-182b-490f-8183-3b8714abc9bc'),  
 'Survey type': 'Airborne TEM',  
 'Transmitters': UUID('10735189-6bf3-42f4-80da-e6f4bcb3345a'),  
 'Unit': 'Milliseconds (ms)'}}`

## Channels

List of time channels at which the data are provided.

[6]: `aem_receivers.channels = np.logspace(-5, -2, 10) # Simple sweep from 1 to 10 ms`

## Input type

Label defining how the survey was created.

- Rx: Survey defined from the `AirborneTEMReceivers` positions, with the `AirborneTEMTransmitters` added from offsets.
- Tx: Survey defined from the `AirborneTEMTransmitters` position, with the `AirborneTEMReceivers` added from offsets.
- Tx and Rx: Survey defined by both the `AirborneTEMTransmitters` and the `AirborneTEMReceivers` positions.

## Property groups

List of `PropertyGroups` defining the various data components (e.g. `dBzdt`, `Bz`, ...). It is expected that each component contains data channels at all times and in the same order as defined in `Channels`.

The class method `add_component_data` can help users add data from nested dictionaries. Below is an example using four components:

```
[7]: # Create some simple data
data_fun = lambda t: 1./ t * np.sin(np.pi * (x_loc * y_loc).ravel() / 800.)

# Create a nested dictionary of time data.
data = {
    "dBdt" : {
        f"time[{tt}]": {"values": data_fun(time)} for tt, time in enumerate(aem_
receivers.channels)
    }
}

aem_receivers.add_components_data(data)

[7]: [<geoh5py.groups.property_group.PropertyGroup at 0x7f16e70873d0>]
```

Metadata are also updated to reflect the addition of component data.

```
[8]: aem_receivers.metadata

[8]: {'EM Dataset': {'Channels': [1e-05,
  2.1544346900318823e-05,
  4.641588833612782e-05,
  0.0001,
  0.00021544346900318823,
  0.00046415888336127773,
  0.001,
  0.002154434690031882,
  0.004641588833612777,
  0.01],
 'Input type': 'Tx and Rx',
 'Property groups': ['dBdt'],
 'Receivers': UUID('c1e8b90a-182b-490f-8183-3b8714abc9bc'),
 'Survey type': 'Airborne TEM',
 'Transmitters': UUID('10735189-6bf3-42f4-80da-e6f4bcb3345a'),
 'Unit': 'Milliseconds (ms)'}}
```

Data channels associated with each component can be quickly accessed through the `BaseEMSurvey.components` property:

```
[9]: aem_receivers.components['dBdt']

[9]: [<geoh5py.data.float_data.FloatData at 0x7f1710153110>,
       <geoh5py.data.float_data.FloatData at 0x7f16e70c0a50>,
       <geoh5py.data.float_data.FloatData at 0x7f16e70c0f10>,
       <geoh5py.data.float_data.FloatData at 0x7f16e70c0950>,
       <geoh5py.data.float_data.FloatData at 0x7f16e7087410>,
       <geoh5py.data.float_data.FloatData at 0x7f16e7087b10>,
       <geoh5py.data.float_data.FloatData at 0x7f16e7087b50>,
       <geoh5py.data.float_data.FloatData at 0x7f16e70870d0>,
       <geoh5py.data.float_data.FloatData at 0x7f16e7087910>,
       <geoh5py.data.float_data.FloatData at 0x7f16e7087ed0>]
```

## Receivers

Generic label used for surveys to identify the receiver entity. References to itself in the case of AirborneTEMReceivers.

## Survey type

Static label identifier for Airborne TEM survey type.

## Transmitters

Generic label used for surveys to identify the transmitter entity. References to itself in the case of AirborneTEMTransmitters.

## Unit

Units for time sampling of the data - must be one of Seconds (s), Milliseconds (ms), Microseconds (us) or Nanoseconds (ns).

## Loop radius

Specifies the transmitter loop radius.

## Custom fields

Metadata are stored in geoh5 as a json structure allowing for custom data fields to be added to the survey. Information such as flight data, date/time, offsets, etc. can be added as `string`, `float` and `int`.

```
[10]: aem_receivers.edit_metadata({"Weather": "sunny"})
```

|atem\custom|

Alternatively, a `uuid.UUID` value can be used if the information is to be provided at every survey position.

```
[11]: # Add a new data entry
abc = aem_receivers.add_data({
    "abc": {"values": np.random.randn(aem_receivers.n_vertices)}
})

# Assign the data as 'Weather' metadata
aem_receivers.edit_metadata({"Weather": abc.uid})
```

Geoscience ANALYST will automatically create a link referencing the data field to the entity in the project tree.

|atem\uid|

## Reserved keywords

For known metadata, such as flight dynamics (`yaw`, `pitch`, `roll`) and offsets (`inline`, `crossline`, `vertical`) the suffix property and value will get replaced based on the input value:

```
[12]: aem_receivers.yaw = 15.
```

|atem\yaw\\_value|

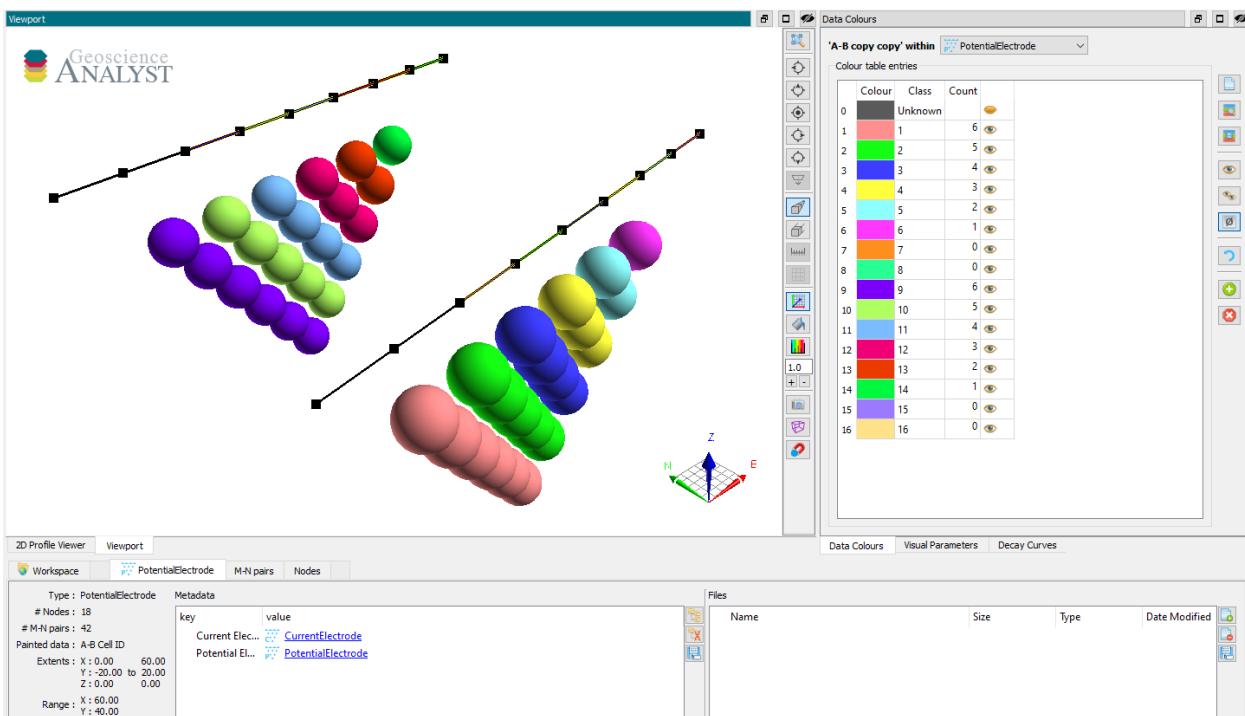

```
[13]: aem_receivers.yaw = abc.uid # Assign to the yaw property
```

|atem\yaw\\_property|

## Direct Current and Induced Polarization (DC-IP)

This survey type is meant to handle direct-current resistivity data. The survey object is made up of two curve entities defining the transmitter (current) and receiver (potential) electrodes.

The following example shows how to generate a DC-IP survey with associated data stored in geoh5 format and accessible from Geoscience ANALYST.

## Current Electrode (transmitters)

The *CurrentElectrode* entity defines the A-B dipole pairs used to inject current into the ground. It is a sub-class of the *PotentialElectrode* object defined by vertices (poles) and cells (dipoles). Here we generate four (4) parallel EW lines with eight dipoles per line.

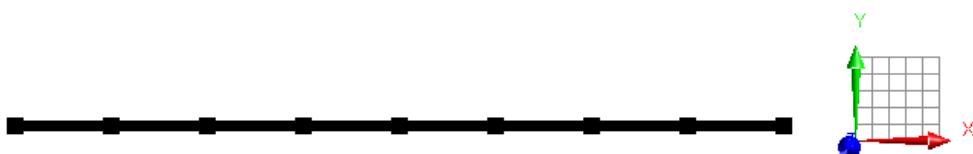

```
[1]: import numpy as np
import uuid
from geoh5py.workspace import Workspace
from geoh5py.objects import CurrentElectrode, PotentialElectrode

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_poles = 9
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_poles), np.linspace(-20, 20, n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_poles)).astype('int')

# Create the CurrentElectrode object
currents = CurrentElectrode.create(workspace, vertices=vertices, parts=parts)
```

At this stage the `CurrentElectrode` object has segments (`cells`) connecting all poles in series along line.

## AB Cell ID

A key element of the DCIP survey objects is the `ab_cell_id` property. This `ReferenceData` contains the map referencing each cell of the `CurrentElectrode` object to a unique A-B source identifier with name.

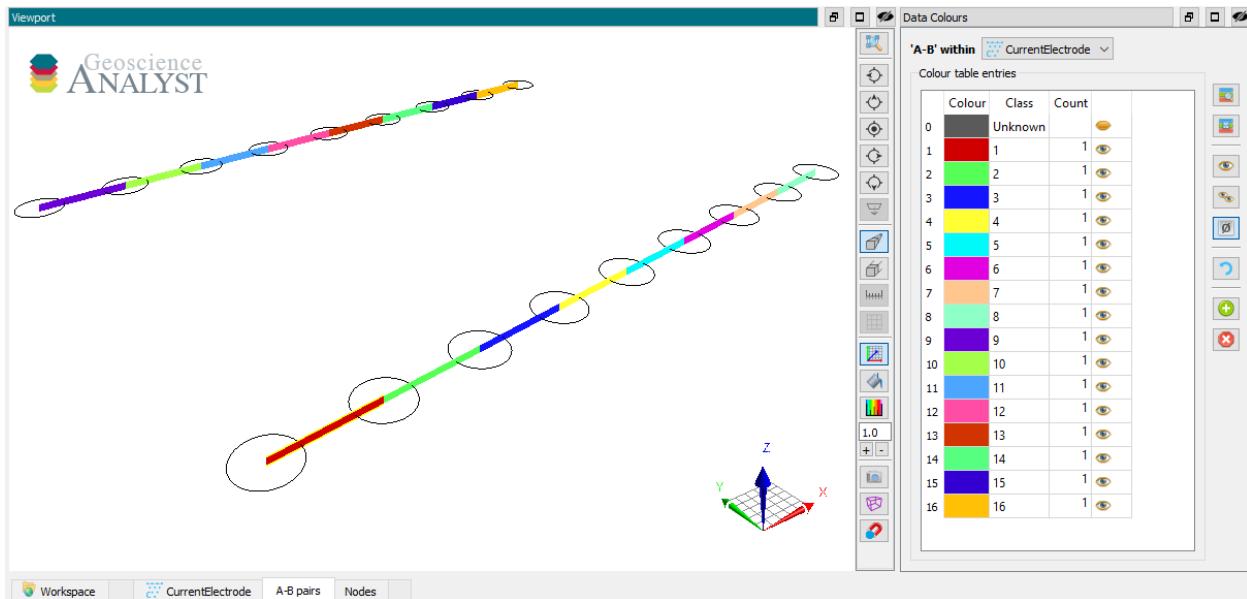

The utility function `add_default_ab_cell_id` can help generate this map with a simple name string incrementor.

```
[2]: currents.add_default_ab_cell_id()
print(currents.ab_cell_id.value_map.map)

{0: 'Unknown', 1: '1', 2: '2', 3: '3', 4: '4', 5: '5', 6: '6', 7: '7', 8: '8', 9: '9',
 10: '10', 11: '11', 12: '12', 13: '13', 14: '14', 15: '15', 16: '16'}
```

/home/docs/checkouts/readthedocs.org/user\_builds/geoh5py/conda/v0.4.0/lib/python3.7/site-packages/geoh5py/data/integer\_data.py:66: UserWarning: Values provided in int64 are converted to int32 for PrimitiveTypeEnum.REFERENCED data 'Entity.'
 f"Values provided in {values.dtype} are converted to int32 for "

In this specific case, every `cell` on the curve corresponds to a unique dipole source current. For more complex survey configurations, users can edit the `cell` property in order to define different combinations of connections between poles.

**Note:** The first entry {0:Unknown} is a reserved field used by Geoscience ANALYST to flag unknown data entries.

### Potential Electrode (receivers)

The *PotentialElectrode* object defines the M-N dipole pairs used to measure the electric potential (receivers). It is a sub-class of the *Curve* object defined by *vertices* (poles) and *cells* (dipoles).

Although poles could be set independently on the *CurrentElectrode* and *PotentialElectrode* objects, here we re-uses the same locations for simplicity:

```
[3]: potentials = PotentialElectrode.create(workspace, vertices=vertices)
```

Next, we must define the receiver dipoles. The following routine generates a maximum of six (6) receivers dipoles per injection currents along line.

```
[4]: N = 6
dipoles = []
current_id = []

for val in currents.ab_cell_id.values: # For each source dipole
    if val == 0: # Skip the unknown
        continue

    cell_id = val - 1 # Python 0 indexing
    line = currents.parts[currents.cells[cell_id, 0]]
    for m_n in range(N):
        dipole_ids = (currents.cells[cell_id, :] + 2 + m_n).astype("uint32") # Skip two poles

        # Shorten the array as we get to the end of the line
        if (
            any(dipole_ids > (potentials.n_vertices - 1))
            or any(currents.parts[dipole_ids] != line)
        ):
            break
```

(continues on next page)

(continued from previous page)

**continue**

```
dipoles += [dipole_ids] # Save the receiver id  
current_id += [val] # Save the source id  
  
potentials.cells = np.vstack(dipoles)
```

Finally, users need to create an association between each receiver dipole (M-N) to a dipole current (A-B). The mapping is done through the `ab_cell_id` property of the `PotentialElectrode`. An integer (ID) value must be assigned to each cell, corresponding to the *AB Cell ID* pairs stored on the associated `CurrentElectrode` object.

```
[5]: potentials.ab_cell_id = np.asarray(current_id, dtype="int32")
```

## Metadata

The link between the sources `CurrentElectrode` and the receivers `PotentialElectrode` is established by the `metadata`, shared by both entities. The connection can be made by assigning `current_electrodes` to the receivers:

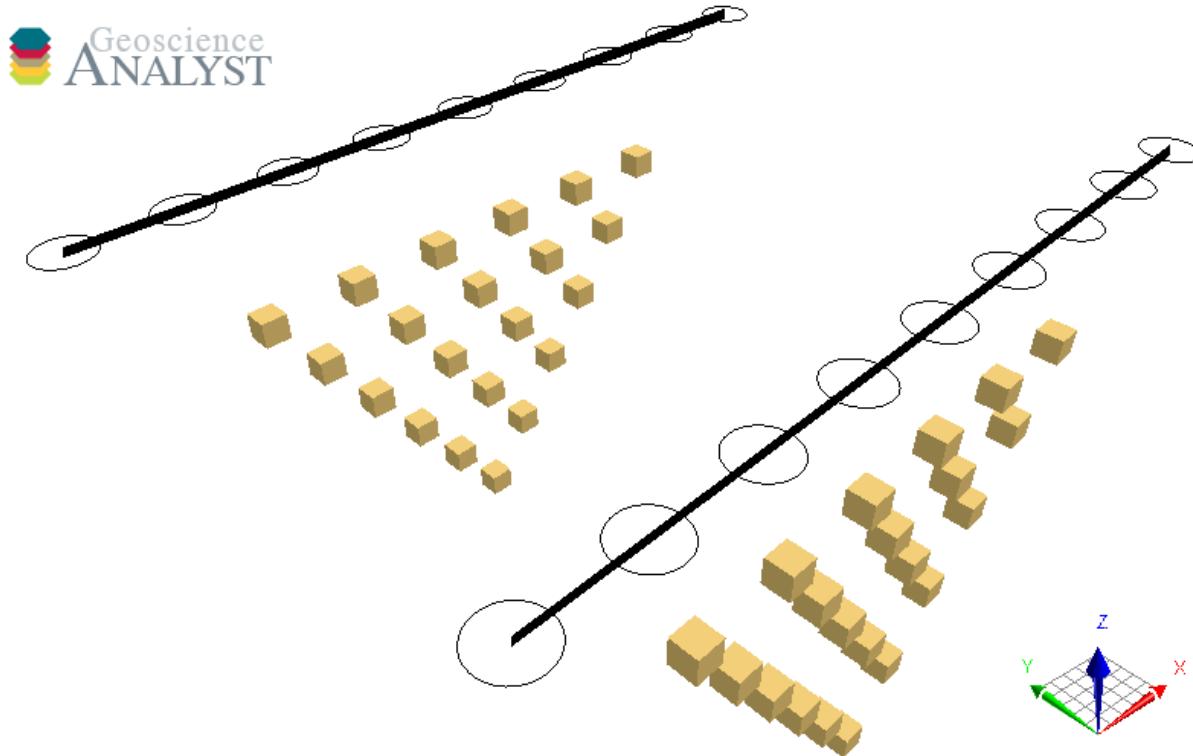

```
[6]: potentials.current_electrodes = currents
```

or equivalently by setting `potential_electrodes` to the currents

```
[7]: currents.potential_electrodes = potentials
```

In both cases, the link between the two objects gets encoded automatically to their respective `metadata`.

```
[8]: print(potentials.metadata == currents.metadata)  
currents.metadata  
  
True  
  
[8]: {'Current Electrodes': UUID('d0a270b1-3ab0-4469-92c2-fdab51fdee53'),  
      'Potential Electrodes': UUID('1cf4525a-d58a-4dbf-8c97-5d3fb77a164c')}
```

Note: The `ab_cell_id` property of the `CurrentElectrode` and `PotentialElectrode` are two different `ReferenceData` entities:

```
[9]: print(potentials.ab_cell_id == currents.ab_cell_id)
```

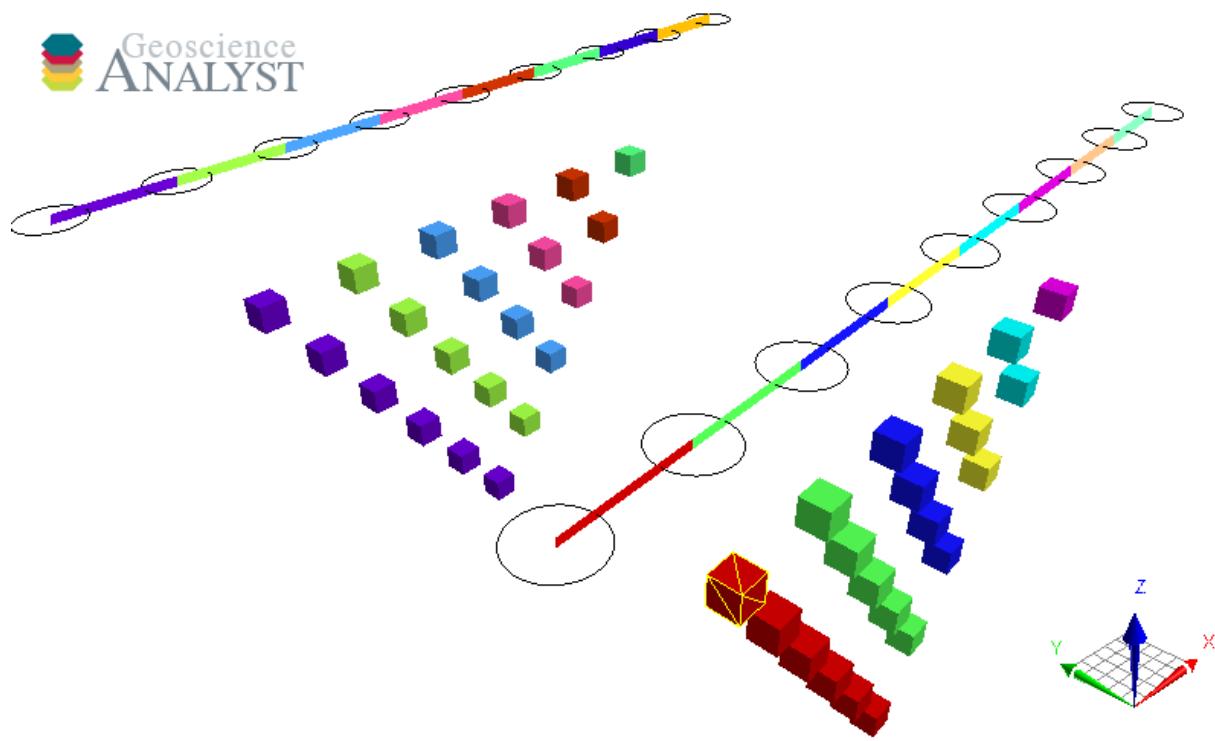

```
False
```

but share the same `DataType` that holds the map of unique source dipoles.

```
[10]: print(potentials.ab_cell_id.entity_type == currents.ab_cell_id.entity_type)
```

```
True
```

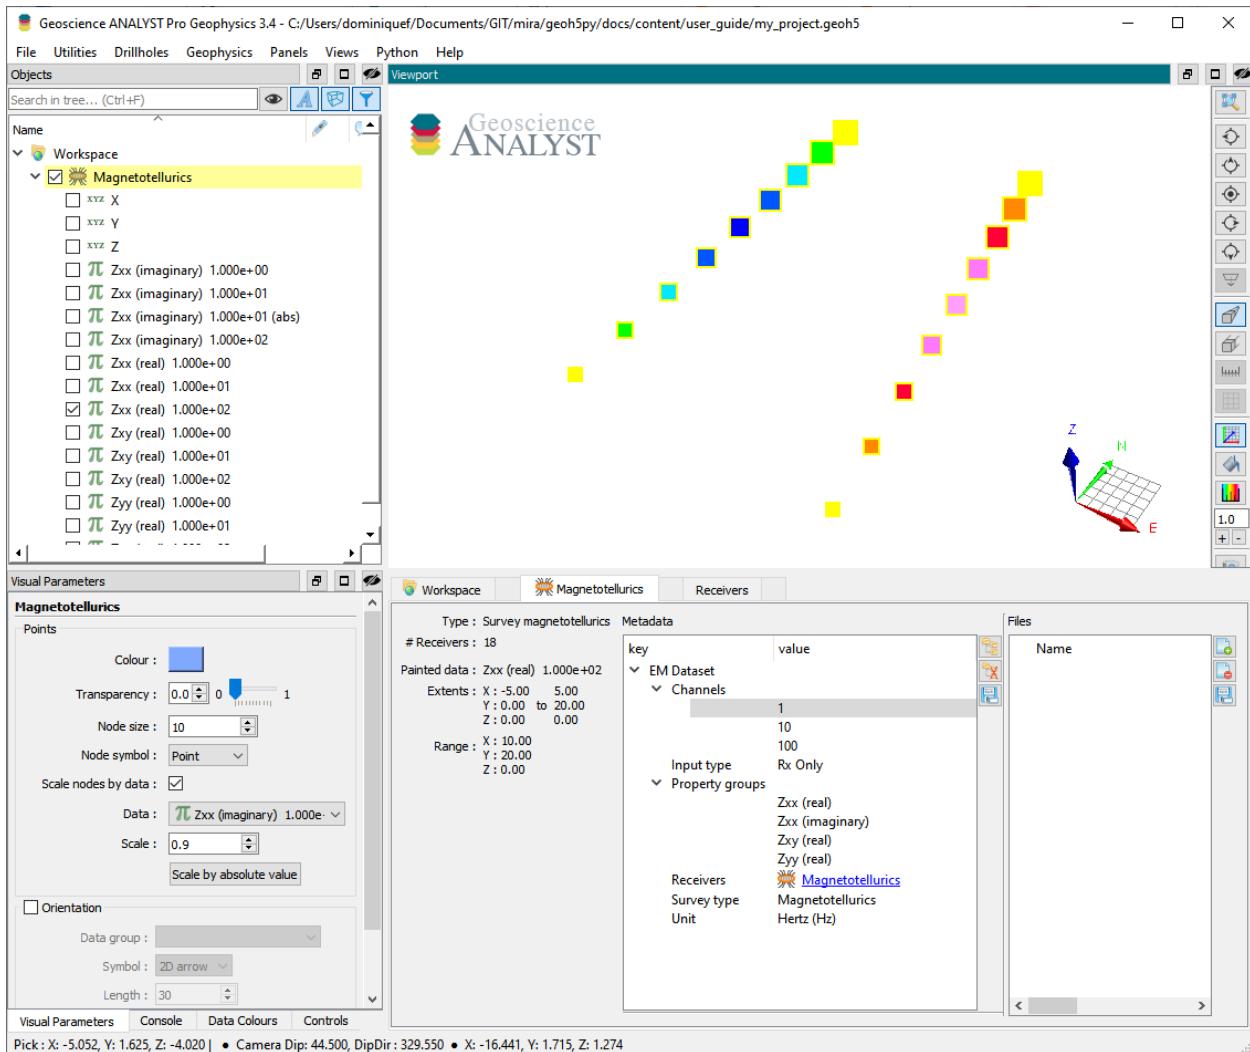

This link between `DataType` allows users to query the data by dipole sources and display the values as pseudo-section in `Geoscience ANALYST`

## Magnetotellurics

This object can be used to store magnetotelluric (MT) surveys - a natural-source geophysical method. Data are provided in the frequency-domain as point source measurements of either impedances or apparent resistivity/phase.

The following example shows how to generate an MT survey with associated data stored in geoh5 format and accessible from [Geoscience ANALYST](#).

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import MTReceivers

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define a synthetic survey with receivers on 2 lines, 60 m apart
x_loc, y_loc = np.meshgrid(np.linspace(-5, 5, 2), np.linspace(0., 20., 9))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Create the survey from vertices
mt_survey = MTReceivers.create(workspace, vertices=vertices)
```

Only receivers are needed to define the survey as MT uses the ambient electromagnetic field of the Earth - no transmitters (source) required.

## Metadata

Along with the *MTReceivers*, the metadata contains all the necessary information to define the geophysical experiment.

```
[2]: mt_survey.metadata  
[2]: {'EM Dataset': {'Channels': [],  
'Input type': 'Rx only',  
'Property groups': [],  
'Receivers': UUID('252a8f8f-6190-455c-bb2e-bee919d4ac90'),  
'Survey type': 'Magnetotellurics',  
'Unit': 'Hertz (Hz)'}}
```

## Channels

List of frequencies at which the data are provided.

```
[3]: mt_survey.channels = [1., 10., 100.]
```

## Input type

Generic label used in the geoh5 standard for all EM survey entities. Restricted to Rx only in the case of natural sources methods.

## Property groups

List of *PropertyGroups* defining the various data components (e.g. Zxx (real), Zxy (imaginary),...). It is not required to supply all components of the impedance tensor, but it is expected that each component contains a list of data channels of length and in the same order as the **Channels** (one Data per frequency).

The class method *add\_components\_data* can help users add data from nested dictionaries. Below is an example using four components:

```
[4]: # Arbitrary data generator using sine functions  
data_fun = lambda c, f: (c+1.) * np.sin(f * np.pi * (x_loc * y_loc).ravel() / 200.)  
  
# Create a nested dictionary of component and frequency data.  
data = {  
    component : {  
        f"component_{freq}": {"values": (ff+1)*1000. + (cc+1) * 100. + np.  
        arange(vertices.shape[0])} for ff, freq in enumerate(mt_survey.channels)  
    } for cc, component in enumerate([  
        "Zxx (real)", "Zxx (imaginary)",  
        "Zxy (real)", "Zxy (imaginary)",  
        "Zyx (real)", "Zyx (imaginary)",  
        "Zyy (real)", "Zyy (imaginary)",  
    ])  
}  
  
mt_survey.add_components_data(data)
```

```
[4]: [<geoh5py.groups.property_group.PropertyGroup at 0x7f9590a38f50>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590a049d0>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590a02ed0>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590a029d0>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590a042d0>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590a07dd0>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f959098d210>,
       <geoh5py.groups.property_group.PropertyGroup at 0x7f9590990450>]
```

Metadata are updated immediately to reflect the addition of components:

```
[5]: mt_survey.metadata
```

```
[5]: {'EM Dataset': {'Channels': [1.0, 10.0, 100.0],
                   'Input type': 'Rx only',
                   'Property groups': ['Zxx (real)',
                                       'Zxx (imaginary)',
                                       'Zxy (real)',
                                       'Zxy (imaginary)',
                                       'Zyx (real)',
                                       'Zyx (imaginary)',
                                       'Zyy (real)',
                                       'Zyy (imaginary)'],
                   'Receivers': UUID('252a8f8f-6190-455c-bb2e-bee919d4ac90'),
                   'Survey type': 'Magnetotellurics',
                   'Unit': 'Hertz (Hz)'}}
```

Data channels associated with each component can be quickly accessed through the `BaseEMSurvey.components` property:

```
[6]: mt_survey.components
```

```
[6]: {'Zxx (real)': [<geoh5py.data.float_data.FloatData at 0x7f95bc37d350>,
                    <geoh5py.data.float_data.FloatData at 0x7f95bc37d690>,
                    <geoh5py.data.float_data.FloatData at 0x7f9590a38f10>],
      'Zxx (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7f9590a38b50>,
                          <geoh5py.data.float_data.FloatData at 0x7f9590a04b50>,
                          <geoh5py.data.float_data.FloatData at 0x7f9590a04d50>],
      'Zxy (real)': [<geoh5py.data.float_data.FloatData at 0x7f9590a04f90>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a02d50>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a02e10>],
      'Zxy (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7f9590a02890>,
                           <geoh5py.data.float_data.FloatData at 0x7f9590a02850>,
                           <geoh5py.data.float_data.FloatData at 0x7f9590a02550>],
      'Zyx (real)': [<geoh5py.data.float_data.FloatData at 0x7f9590a02050>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a04210>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a04110>],
      'Zyx (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7f9590a38250>,
                           <geoh5py.data.float_data.FloatData at 0x7f9590a07f10>,
                           <geoh5py.data.float_data.FloatData at 0x7f9590a07d10>],
      'Zyy (real)': [<geoh5py.data.float_data.FloatData at 0x7f9590a0b0d0>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a0bf0d0>,
                     <geoh5py.data.float_data.FloatData at 0x7f9590a0bf10>],
      'Zyy (imaginary)': [<geoh5py.data.float_data.FloatData at 0x7f959098d090>,
```

(continues on next page)

(continued from previous page)

```
<geoh5py.data.float_data.FloatData at 0x7f9590990290>,
<geoh5py.data.float_data.FloatData at 0x7f95909903d0>] }
```

## Receivers

Generic label used in the geoh5 standard for EM survey to identify the receiver entity. Restricted to itself in the case of **MTReceivers**.

## Survey type

Label identifier for **Magnetotellurics** survey type.

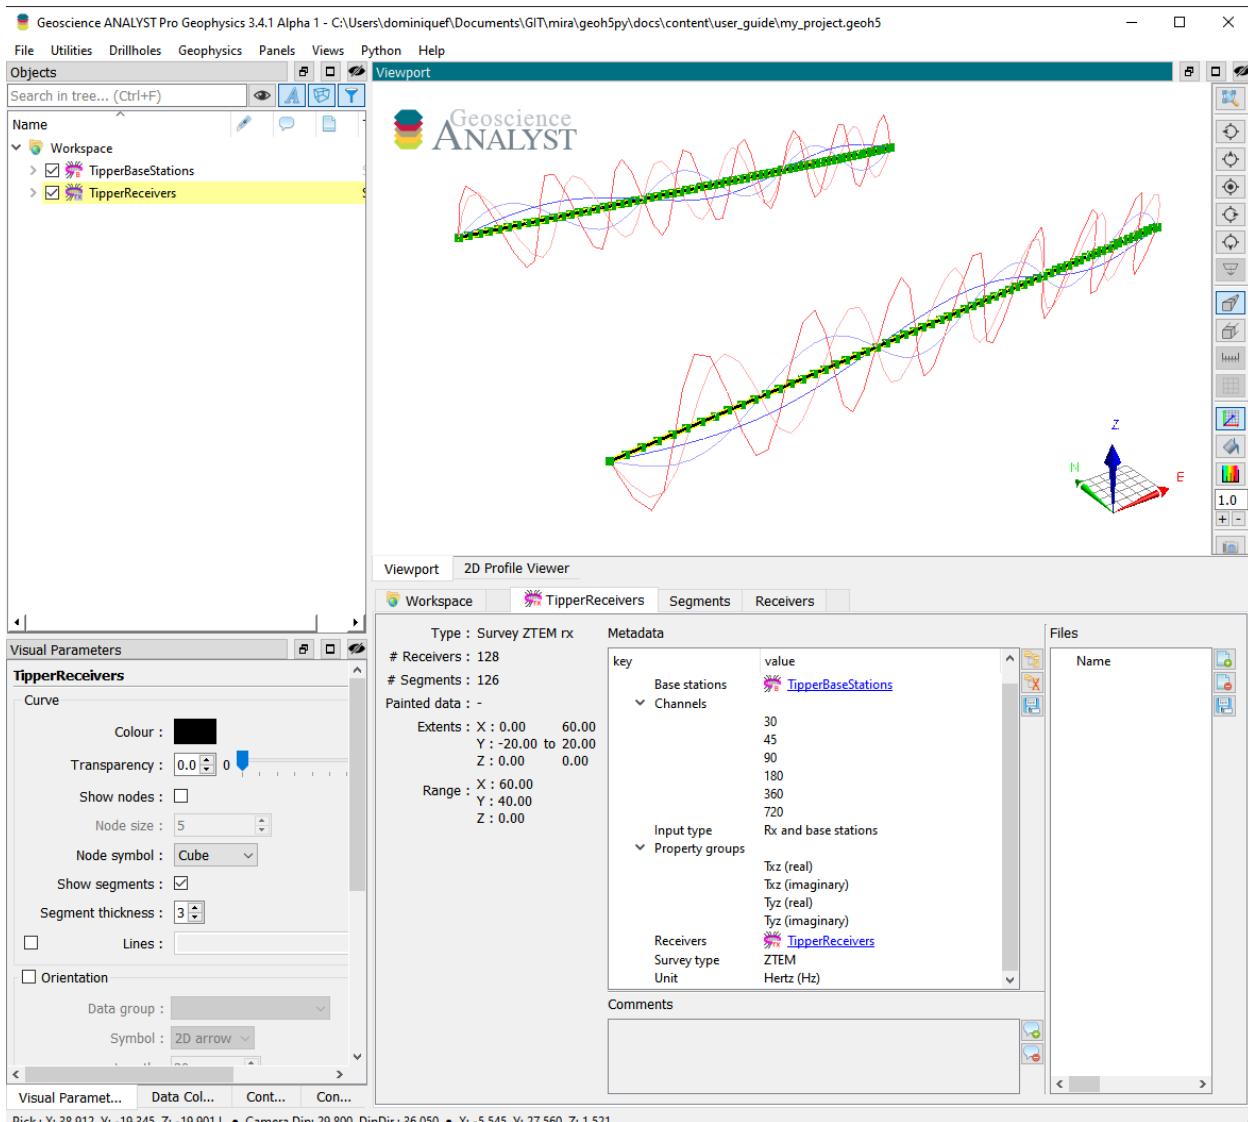

## Unit

Units for frequency sampling of the data: **Hertz** (Hz), **KiloHertz** (kHz), **MegaHertz** (MHz) or **Gigahertz** (GHz).

## Tipper

This object can be used to store tipper (ZTEM) surveys - a natural-source geophysical method. Data are provided in the frequency-domain as point source measurements of tipper data.

The following example shows how to generate a tipper survey with associated data stored in geoh5 format and accessible from **Geoscience ANALYST**.

```
[1]: import numpy as np
from geoh5py.workspace import Workspace
from geoh5py.objects import Tipperreceivers, TipperBaseStations

# Create a new project
workspace = Workspace("my_project.geoh5")

# Define the pole locations
n_stations = 64
n_lines = 2
x_loc, y_loc = np.meshgrid(np.linspace(0, 60, n_stations), np.linspace(-20, 20., n_lines))
vertices = np.c_[x_loc.ravel(), y_loc.ravel(), np.zeros_like(x_loc).ravel()]

# Assign a line ID to the poles (vertices)
parts = np.kron(np.arange(n_lines), np.ones(n_stations)).astype('int')
```

(continues on next page)

(continued from previous page)

```
# Create the survey from vertices
receivers = TipperReceivers.create(workspace, vertices=vertices, parts=parts)
base = TipperBaseStations.create(workspace, vertices=vertices)
```

We have so far created two separate entities, one for the receiver locations and another for the base station(s). In order to finalize the survey, the association must be made between the two entities:

```
[2]: receivers.base_station = base
```

or equivalently

```
[3]: base.receivers = receivers
```

Only one of the two options above is needed.

## Metadata

Along with the *TipperReceivers*, the metadata contains all the necessary information to define the geophysical experiment.

```
[4]: receivers.metadata
```

```
[4]: {'EM Dataset': {'Base stations': UUID('71af3957-9acc-49bb-8eda-62c507ec51e3'),
  'Channels': [],
  'Input type': 'Rx and base stations',
  'Property groups': [],
  'Receivers': UUID('5749d43d-fe67-4712-9010-02dc3bf2dbe8'),
  'Survey type': 'ZTEM',
  'Unit': 'Hertz (Hz)'}}
```

## Channels

List of frequencies at which the data are provided.

```
[5]: receivers.channels = [30., 45., 90., 180., 360., 720.]
```

## Input type

Generic label used in the geoh5 standard for all EM survey entities. Restricted to Rx and base station in the case of a tipper survey.

## Property groups

List of *PropertyGroups* defining the various data components (e.g. Txz (real), Tyz (imaginary), ...). It is not required to supply all components of the impedance tensor, but it is expected that each component contains a list of data channels of length and in the same order as the `Channels` (one Data per frequency).

The class method `add_components_data` can help users add data from nested dictionaries. Below is an example using four components:

```
[6]: # Arbitrary data generator using sine functions
data_fun = lambda c, f: (c+1.) * (f+1.) * np.sin(f * np.pi * (x_loc * y_loc).ravel() / 400.)

# Create a nested dictionary of component and frequency data.
data = {
    component : {
        f"component_{freq}": {"values": data_fun(cc, ff)} for ff, freq in
        enumerate(receivers.channels)
    } for cc, component in enumerate([
        "Txz (real)", "Txz (imaginary)",
        "Tyz (real)", "Tyz (imaginary)",
    ])
}
receivers.add_components_data(data)

[6]: [<geoh5py.groups.property_group.PropertyGroup at 0x7f05d0ed3850>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f05d0dc1850>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f05d0e25590>,
<geoh5py.groups.property_group.PropertyGroup at 0x7f05d0dc4b50>]
```

Metadata are updated immediately to reflect the addition of components:

```
[7]: receivers.metadata

[7]: {'EM Dataset': {'Base stations': UUID('71af3957-9acc-49bb-8eda-62c507ec51e3'),
  'Channels': [30.0, 45.0, 90.0, 180.0, 360.0, 720.0],
  'Input type': 'Rx and base stations',
  'Property groups': ['Txz (real)',
    'Txz (imaginary)',
    'Tyz (real)',
    'Tyz (imaginary)']},
  'Receivers': UUID('5749d43d-fe67-4712-9010-02dc3bf2dbe8'),
  'Survey type': 'ZTEM',
  'Unit': 'Hertz (Hz)'}}
```

Data channels associated with each component can be quickly accessed through the `BaseEMSurvey.components` property:

```

```

## Receivers

Generic label used in the geoh5 standard for EM survey to identify the *TipperReceivers* entity.

## Base stations

Generic label used in the geoh5 standard for EM survey to identify the *TipperBaseStations* entity.

## Survey type

Label identifier for ZTEM survey type.

## Unit

Units for frequency sampling of the data: Hertz (Hz), KiloHertz (kHz), MegaHertz (MHz) or Gigahertz (GHz).

```

/home/docs/checkouts/readthedocs.org/user_builds/geoh5py/conda/v0.4.0/lib/python3.7/site-
    packages/geoh5py/workspace/workspace.py:817: UserWarning: The 'finalize' method will
    be deprecated in future versions of geoh5py in favor of `workspace.close()`. Please
    update your code to suppress this warning.
    "The 'finalize' method will be deprecated in future versions of geoh5py in"
```

## 2.3 geoh5py

### 2.3.1 geoh5py.data

#### geoh5py.data.blob\_data

```
class geoh5py.data.blob_data.BlobData(data_type: DataType, **kwargs)
    Bases: Data
    classmethod primitive_type() → PrimitiveTypeEnum
```

#### geoh5py.data.color\_map

```
class geoh5py.data.color_map.ColorMap(**kwargs)
    Bases: object
    Records colors assigned to value ranges (where Value is the start of the range).
    property name: str
        str: Name of the colormap
    property parent
        Parent data type
    property values: np.ndarray | None
        numpy.array: Colormap defined by values and corresponding RGBA:
```

```
values = [
    [V_1, R_1, G_1, B_1, A_1],
    ..., [V_i, R_i, G_i, B_i, A_i]
]
```

where V (Values) are sorted floats defining the position of each RGBA. R (Red), G (Green), B (Blue) and A (Alpha) are integer values between [0, 255].

#### geoh5py.data.data

```
class geoh5py.data.data.Data(data_type: DataType, **kwargs)
```

Bases: Entity

Base class for Data entities.

**add\_file(file: str)**

Alias not implemented from base Entity class.

**property association: DataAssociationEnum | None**

*DataAssociationEnum*: Relationship made between the `values()` and elements of the `parent` object.  
Association can be set from a `str` chosen from the list of available `DataAssociationEnum` options.

**property entity\_type: DataType**

*DataType*

**property modifiable: bool**

bool Entity can be modified.

```
property n_values: int | None
    int: Number of expected data values based on association
abstract classmethod primitive_type() → PrimitiveTypeEnum
remove_data_from_group(data: list | Entity | uuid.UUID | str, name: str = None)
    Remove self from a property group.
property values
    Data values
```

## geoh5py.data.data\_association\_enum

```
class geoh5py.data.data_association_enum.DataAssociationEnum(value)
Bases: Enum
Known data association between values and the parent object. Available options:
CELL = 2
DEPTH = 6
FACE = 4
GROUP = 5
OBJECT = 1
UNKNOWN = 0
VERTEX = 3
```

## geoh5py.data.data\_type

```
class geoh5py.data.data_type.DataType(workspace: workspace.Workspace, **kwargs)
```

Bases: *EntityType*

DataType class

property color\_map: ColorMap | None

*ColorMap*: Colormap used for plotting

The colormap can be set from a dict of sorted values with corresponding RGBA color.

```
color_map = {
    val_1: [r_1, g_1, b_1, a_1],
    ...,
    val_i: [r_i, g_i, b_i, a_i]
}
```

```
classmethod create(workspace: workspace.Workspace, data_class: type[Data]) → DataType
```

Creates a new instance of *DataType* with corresponding *PrimitiveTypeEnum*.

**Parameters**

**data\_class** – A *Data* implementation class.

**Returns**

A new instance of `DataType`.

**classmethod** `find_or_create(workspace: workspace.Workspace, **kwargs) → DataType`

Find or creates an EntityType with given UUID that matches the given Group implementation class.

**Parameters**

`workspace` – An active Workspace class

**Returns**

A new instance of `DataType`.

**classmethod** `for_x_data(workspace: workspace.Workspace) → DataType`

**classmethod** `for_y_data(workspace: workspace.Workspace) → DataType`

**classmethod** `for_z_data(workspace: workspace.Workspace) → DataType`

**property** `hidden: bool`

`bool`: Hidden data [False]

**property** `mapping: str`

`str`: Color stretching type chosen from: ‘linear’, ['equal\_area'], ‘logarithmic’, ‘cdf’, ‘missing’

**property** `number_of_bins: int | None`

`int`: Number of bins used by the histogram [50]

**property** `primitive_type: PrimitiveTypeEnum | None`

`PrimitiveTypeEnum`

**property** `transparent_no_data: bool`

`bool`: Use transparent for no-data-value [True]

**property** `units: str | None`

`str`: Data units

**property** `value_map: ReferenceValueMap | None`

`ReferenceValueMap`: Reference value map for `ReferenceData`

The `value_map` can be set from a `dict` of sorted values with corresponding `str` description.

```
value_map = {
    val_1: str_1,
    ...,
    val_i: str_i
}
```

## geoh5py.data.data\_unit

**class** `geoh5py.data.data_unit.DataUnit(unit_name: Optional[str] = None)`

Bases: `object`

Data unit

**property** `name: str | None`

## geoh5py.data.datetime\_data

```
class geoh5py.data.datetime_data.DatetimeData(data_type: DataType, **kwargs)
```

Bases: *Data*

```
classmethod primitive_type() → PrimitiveTypeEnum
```

## geoh5py.data.filename\_data

```
class geoh5py.data.filename_data.FilenameData(data_type: DataType, file_name=None, **kwargs)
```

Bases: *Data*

```
property file_name: str | None
```

str Text value.

```
classmethod primitive_type() → PrimitiveTypeEnum
```

```
save_file(path: str = '.', name=None)
```

Save the file to disk.

### Parameters

- **path** – Directory to save the file to.
- **name** – Name given to the file.

```
property values: bytes | None
```

Binary str value representation of a file.

## geoh5py.data.float\_data

```
class geoh5py.data.float_data.FloatData(data_type: DataType, **kwargs)
```

Bases: *NumericData*

Data container for floats values

```
property ndv: float
```

No-Data-Value

```
classmethod primitive_type() → PrimitiveTypeEnum
```

## geoh5py.data.geometric\_data\_constants

```
class geoh5py.data.geometric_data_constants.GeometricDataConstants
```

Bases: *object*

```
classmethod primitive_type() → PrimitiveTypeEnum
```

```
classmethod x_datatype_uid() → UUID
```

```
classmethod y_datatype_uid() → UUID
```

```
classmethod z_datatype_uid() → UUID
```

## geoh5py.data.integer\_data

```
class geoh5py.data.integer_data.IntegerData(data_type: DataType, **kwargs)
```

Bases: *NumericData*

**property ndv: int**

No-Data-Value

```
classmethod primitive_type() → PrimitiveTypeEnum
```

**property values: np.ndarray | None**

**Returns**

values: An array of integer values

## geoh5py.data.numeric\_data

```
class geoh5py.data.numeric_data.NumericData(data_type: DataType, **kwargs)
```

Bases: *Data*, ABC

Data container for floats values

```
check_vector_length(values) → ndarray
```

Check for possible mismatch between the length of values stored and the expected number of cells or vertices.

**abstract property ndv**

No-data-value

```
classmethod primitive_type() → PrimitiveTypeEnum
```

**property values: np.ndarray | None**

**Returns**

values: An array of float values

## geoh5py.data.primitive\_type\_enum

```
class geoh5py.data.primitive_type_enum.PrimitiveTypeEnum(value)
```

Bases: *Enum*

Known data type.

Available options:

**BLOB = 6**

**DATETIME = 8**

**FILENAME = 5**

**FLOAT = 2**

**GEOMETRIC = 9**

**INTEGER = 1**

```
INVALID = 0
MULTI_TEXT = 10
REFERENCED = 4
TEXT = 3
VECTOR = 7
```

## geoh5py.data.reference\_value\_map

```
class geoh5py.data.reference_value_map.ReferenceValueMap(color_map: dict[int, str] = None)
```

Bases: ABC

Maps from reference index to reference value of ReferencedData.

### property map

dict: A reference dictionary mapping values to strings

## geoh5py.data.referenced\_data

```
class geoh5py.data.referenced_data.ReferencedData(data_type: DataType, **kwargs)
```

Bases: *IntegerData*

Reference data described by indices and associated strings.

```
classmethod primitive_type() → PrimitiveTypeEnum
```

### property value\_map

Pointer to the data.data\_type.DataType.value\_map

## geoh5py.data.text\_data

```
class geoh5py.data.text_data.CommentsData(data_type: DataType, **kwargs)
```

Bases: *Data*

Comments added to an Object or Group. Stored as a list of dictionaries with the following keys:

```
comments = [
    {
        "Author": "username",
        "Date": "2020-05-21T10:12:15",
        "Text": "A text comment."
    },
]
```

```
classmethod primitive_type() → PrimitiveTypeEnum
```

```
property values: list[dict] | None
```

list List of comments

```
class geoh5py.data.text_data.MultiTextData(data_type: DataType, **kwargs)
```

Bases: *Data*

```
classmethod primitive_type() → PrimitiveTypeEnum  
property values: np.ndarray | str | None  
    str Text value.  
  
class geoh5py.data.text_data.TextData(data_type: DataType, **kwargs)  
    Bases: Data  
    classmethod primitive_type() → PrimitiveTypeEnum  
    property values: np.ndarray | str | None  
        str Text value.
```

## geoh5py.data.unknown\_data

```
class geoh5py.data.unknown_data.UnknownData(data_type: DataType, association: DataAssociationEnum,  
                                              name: str, uid: Optional[UUID] = None)  
    Bases: Data  
    classmethod primitive_type() → PrimitiveTypeEnum
```

## 2.3.2 geoh5py.groups

### geoh5py.groups.container\_group

```
class geoh5py.groups.container_group.ContainerGroup(group_type: GroupType, **kwargs)  
    Bases: Group  
    The type for the basic Container group.  
    classmethod default_type_uid() → UUID
```

### geoh5py.groups.custom\_group

```
class geoh5py.groups.custom_group.CustomGroup(group_type: GroupType, **kwargs)  
    Bases: Group  
    A custom group, for an unlisted Group type.  
    classmethod default_type_uid() → uuid.UUID | None
```

### geoh5py.groups.drillhole\_group

```
class geoh5py.groups.drillhole_group.DrillholeGroup(group_type: GroupType, name='Drillholes  
Group', **kwargs)  
    Bases: Group  
    The type for the group containing drillholes.  
    classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.drillhole_group.IntegratorDrillholeGroup(group_type: GroupType,  
**kwargs)
```

Bases: *DrillholeGroup*

The type for the group containing drillholes.

```
classmethod default_type_uid() → UUID
```

## geoh5py.groups.giftools\_group

```
class geoh5py.groups.giftools_group.GiftoolsGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a GIFTools group.

```
classmethod default_type_uid() → UUID
```

## geoh5py.groups.group

```
class geoh5py.groups.group.Group(group_type: GroupType, **kwargs)
```

Bases: *Entity*

Base Group class

```
add_comment(comment: str, author: Optional[str] = None)
```

Add text comment to an object.

### Parameters

- **comment** – Text to be added as comment.
- **author** – Author's name or contributors.

### property comments

Fetch a *CommentsData* entity from children.

```
abstract classmethod default_type_uid() → uuid.UUID | None
```

### property entity\_type: *GroupType*

```
classmethod find_or_create_type(workspace: workspace.Workspace, **kwargs) → GroupType
```

## geoh5py.groups.group\_type

```
class geoh5py.groups.group_type.GroupType(workspace: workspace.Workspace, **kwargs)
```

Bases: *EntityType*

### property allow\_delete\_content: bool

bool: [True] Allow to delete the group *children*.

### property allow\_move\_content: bool

bool: [True] Allow to move the group *children*.

```
static create_custom(workspace: workspace.Workspace, **kwargs) → GroupType
```

Creates a new instance of GroupType for an unlisted custom Group type with a new auto-generated UUID.

```
classmethod find_or_create(workspace: workspace.Workspace, entity_class, **kwargs) → GroupType
```

Find or creates an EntityType with given UUID that matches the given Group implementation class.

#### Parameters

- **workspace** – An active Workspace class
- **entity\_class** – An Group implementation class.

#### Returns

A new instance of GroupType.

## geoh5py.groups.integrator\_group

```
class geoh5py.groups.integrator_group.AirborneTheme(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Airborne Theme.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.EarthModelsTheme(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Earth Models Theme.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.GeochemistryMineralogyDataSet(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Geochemistry & Mineralogy DataSet.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.GeochemistryMineralogyTheme(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Geochemistry & Mineralogy Theme.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.GeophysicsTheme(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Geophysics Theme.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.GroundTheme(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for a INTEGRATOR Ground Theme.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.groups.integrator_group.IntegratorGroup(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR group.

@classmethod default_type_uid() → UUID

class geoh5py.groups.integrator_group.IntegratorProject(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR group.

@classmethod default_type_uid() → UUID

class geoh5py.groups.integrator_group.ObservationPointsTheme(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR Observation Points Theme.

@classmethod default_type_uid() → UUID

class geoh5py.groups.integrator_group.QueryGroup(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR Query Group.

@classmethod default_type_uid() → UUID

class geoh5py.groups.integrator_group.RockPropertiesTheme(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR Rock Properties Theme.

@classmethod default_type_uid() → UUID

class geoh5py.groups.integrator_group.SamplesTheme(group_type: GroupType, **kwargs)
Bases: Group

The type for a INTEGRATOR Samples Theme.

@classmethod default_type_uid() → UUID
```

## geoh5py.groups.maps\_group

```
class geoh5py.groups.maps_group.MapsGroup(group_type: GroupType, **kwargs)
Bases: Group

The type for the basic Container group.

@classmethod default_type_uid() → UUID
```

### geoh5py.groups.notype\_group

```
class geoh5py.groups.notype_group.NoTypeGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

A group with no type.

```
classmethod default_type_uid() → UUID
```

### geoh5py.groups.property\_group

```
class geoh5py.groups.property_group.PropertyGroup(**kwargs)
```

Bases: ABC

Property group listing data children of an object. This group is not registered to the workspace and only visible to the parent object.

```
property association: DataAssociationEnum
```

*DataAssociationEnum* Data association

```
property attribute_map: dict
```

dict Attribute names mapping between geoh5 and geoh5py

```
property name: str
```

str Name of the group

```
property parent: Entity
```

The parent *ObjectBase*

```
property properties: list[uuid.UUID]
```

List of unique identifiers for the *Data* contained in the property group.

```
property property_group_type: str
```

```
property uid: UUID
```

uuid.UUID Unique identifier

### geoh5py.groups.root\_group

```
class geoh5py.groups.root_group.RootGroup(group_type: GroupType, **kwargs)
```

Bases: *NoTypeGroup*

The Root group of a workspace.

```
property parent
```

Parental entity of root is always None

## geoh5py.groups.simpeg\_group

```
class geoh5py.groups.simpeg_group.SimPEGGroup(group_type: GroupType, **kwargs)
```

Bases: *Group*

Group for SimPEG inversions.

```
classmethod default_type_uid() → UUID
```

```
property options: dict | None
```

Metadata attached to the entity.

## geoh5py.groups.survey\_group

```
class geoh5py.groups.survey_group.AirborneGeophysics(group_type: GroupType, **kwargs)
```

Bases: *Group*

The type for the basic Container group.

```
classmethod default_type_uid() → UUID
```

### 2.3.3 geoh5py.io

#### geoh5py.io.h5\_reader

```
class geoh5py.io.h5_reader.H5Reader
```

Bases: *object*

Class to read information from a geoh5 file.

```
classmethod fetch_array_attribute(file: str | h5py.File, uid: uuid.UUID, entity_type: str, key: str) → np.ndarray | None
```

Get an entity attribute stores as array such as `cells`.

##### Parameters

- **file** – `h5py.File` or name of the target geoh5 file
- **uid** – Unique identifier of the target object.
- **entity\_type** – Group type to fetch entity from.
- **key** – Field attribute name.

##### Return `cells`

`numpy.ndarray` of `int`.

```
classmethod fetch_attributes(file: str | h5py.File, uid: uuid.UUID, entity_type: str) → tuple[dict, dict, dict]
```

Get attributes of an `Entity`.

##### Parameters

- **file** – `h5py.File` or name of the target geoh5 file
- **uid** – Unique identifier
- **entity\_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group\_type’, ‘data\_type’, ‘object\_type’

## Returns

### attributes:

[obj:dict of attributes for the *Entity*]

### type\_attributes:

[obj:dict of attributes for the *EntityType*]

### property\_groups:

[obj:dict of data `uuid.UUID`]

**classmethod** `fetch_children(file: str | h5py.File, uid: uuid.UUID, entity_type: str) → dict`

Get `children` of an *Entity*.

## Parameters

- **file** – `h5py.File` or name of the target geoh5 file
- **uid** – Unique identifier
- **entity\_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group\_type’, ‘data\_type’, ‘object\_type’

### Return children

[{`uid: type`}, ...] List of dictionaries for the children uid and type

**classmethod** `fetch_concatenated_attributes(file: str | h5py.File, uid: uuid.UUID, entity_type: str, label: str) → list | dict | None`

Get ‘Attributes’, ‘Data’ or ‘Index’ from Concatenator group.

## Parameters

- **file** – `h5py.File` or name of the target geoh5 file
- **uid** – Unique identifier
- **entity\_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group\_type’, ‘data\_type’, ‘object\_type’
- **label** – Group identifier for the attribute requested.

### Return children

[{`uid: type`}, ...] List of dictionaries for the children uid and type

**classmethod** `fetch_concatenated_values(file: str | h5py.File, uid: uuid.UUID, entity_type: str, label: str) → tuple | None`

Get `children` values of concatenated group.

## Parameters

- **file** – `h5py.File` or name of the target geoh5 file
- **uid** – Unique identifier
- **entity\_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group\_type’, ‘data\_type’, ‘object\_type’
- **label** – Group identifier for the attribute requested.

### Return children

[{`uid: type`}, ...] List of dictionaries for the children uid and type

**classmethod fetch\_file\_object**(*file*: str | h5py.File, *uid*: uuid.UUID, *file\_name*: str) → bytes | None

Load data associated with an image file

**Parameters**

- **file** – Name of the target geoh5 file
- **uid** – Unique identifier of the target entity
- **file\_name** – Name of the file stored as bytes data.

**Return values**

Data file stored as bytes

**classmethod fetch\_metadata**(*file*: str | h5py.File, *uid*: uuid.UUID, *entity\_type*: str = 'Objects', *argument*: str = 'Metadata') → str | dict | None

Fetch text of dictionary type attributes of an entity.

**Parameters**

- **file** – Target h5 file.
- **uid** – Unique identifier of the target Entity.
- **entity\_type** – Base type of the target Entity.
- **argument** – Label name of the dictionary.

**classmethod fetch\_project\_attributes**(*file*: str | h5py.File) → dict[Any, Any]

Get attributes of an *Entity*.

**Parameters**

**file** – h5py.File or name of the target geoh5 file

**Return attributes**

dict of attributes.

**classmethod fetch\_property\_groups**(*file*: str | h5py.File, *uid*: uuid.UUID) → dict[str, dict[str, str]]

Get the property groups.

**Parameters**

- **file** – h5py.File or name of the target geoh5 file
- **uid** – Unique identifier of the target entity

**Return property\_group\_attributes**

dict of property groups and respective attributes.

```
property_group = {
    "group_1": {"attribute": value, ...},
    ...,
    "group_N": {"attribute": value, ...},
}
```

**classmethod fetch\_type**(*file*: str | h5py.File, *uid*: uuid.UUID, *entity\_type*: str) → dict

Fetch a type from the target geoh5.

**Parameters**

- **file** – h5py.File or name of the target geoh5 file
- **uid** – Unique identifier of the target entity

- **entity\_type** – One of ‘Data’, ‘Object’ or ‘Group’

**Return property\_group\_attributes**

dict of property groups and respective attributes.

**classmethod fetch\_type\_attributes**(*type\_handle*: *Group*) → dict

Fetch type attributes from a given h5 handle.

**classmethod fetch\_uuids**(*file*: str | *h5py.File*, *entity\_type*: str) → list

Fetch all uuids of a given type from geoh5

**Parameters**

- **file** – *h5py.File* or name of the target geoh5 file
- **entity\_type** – Type of entity from ‘group’, ‘data’, ‘object’, ‘group\_type’, ‘data\_type’, ‘object\_type’

**Return uuids**

[uuid1, uuid2, ...] List of uuids

**classmethod fetch\_value\_map**(*h5\_handle*: *Group*) → dict

Get data value\_map

**Parameters**

**h5\_handle** – Handle to the target h5 group.

**Return value\_map**

dict of {int: str}

**classmethod fetch\_values**(*file*: str | *h5py.File*, *uid*: *uuid.UUID*) → np.ndarray | str | float | None

Get data values

**Parameters**

- **file** – *h5py.File* or name of the target geoh5 file
- **uid** – Unique identifier of the target entity

**Return values**

*numpy.array* of float

**static format\_type\_string**(*string*: str) → str

Format names used for types.

## geoh5py.io.h5\_writer

**class geoh5py.io.h5\_writer.H5Writer**

Bases: object

Writing class to a geoh5 file.

**classmethod clear\_stats\_cache**(*file*: str | *h5py.File*, *entity*: Data) → None

Clear the StatsCache dataset.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.

**classmethod** `create_dataset(entity_handle, dataset: ndarray, label: str) → None`

Create a dataset on geoh5.

**Parameters**

- **entity\_handle** – Pointer to a hdf5 group
- **dataset** – Array of values to be written
- **label** – Name of the dataset on file

**classmethod** `create_geoh5(file: str | h5py.File, workspace: workspace.Workspace)`

Add the geoh5 core structure.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **workspace** – `Workspace` object defining the project structure.

**Return h5file**

Pointer to a geoh5 file.

**classmethod** `fetch_handle(file: str | h5py.File, entity, return_parent: bool = False) → None | h5py.Group`

Get a pointer to an `Entity` in geoh5.

**Parameters**

- **file** – Name or handle to a geoh5 file
- **entity** – Target `Entity`
- **return\_parent** – Option to return the handle to the parent entity.

**Return entity\_handle**

HDF5 pointer to an existing entity, parent or None if not found.

**static** `remove_child(file: str | h5py.File, uid: uuid.UUID, ref_type: str, parent: Entity) → None`

Remove a child from a parent.

**Parameters**

- **file** – Name or handle to a geoh5 file
- **uid** – uuid of the target `Entity`
- **ref\_type** – Input type from: ‘Types’, ‘Groups’, ‘Objects’ or ‘Data’
- **parent** – Remove entity from parent.

**static** `remove_entity(file: str | h5py.File, uid: uuid.UUID, ref_type: str, parent: Entity = None) → None`

Remove an entity and its type from the target geoh5 file.

**Parameters**

- **file** – Name or handle to a geoh5 file
- **uid** – uuid of the target `Entity`
- **ref\_type** – Input type from: ‘Types’, ‘Groups’, ‘Objects’ or ‘Data’
- **parent** – Remove entity from parent.

```
classmethod save_entity(file: str | h5py.File, entity, add_children: bool = True) → h5py.Group
```

Write an [Entity](#) to geoh5 with its [children](#).

#### Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target [Entity](#).
- **add\_children** – Add [children](#).

```
str_type = dtype('O')
```

```
classmethod update_concatenated_field(file: str | h5py.File, entity, attribute: str, channel: str) → None
```

Update the attributes of a concatenated [Entity](#).

#### Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target [Entity](#).
- **attribute** – Name of the attribute to get updated.
- **channel** – Name of the data or index to be modified.

```
classmethod update_field(file: str | h5py.File, entity, attribute: str, **kwargs) → None
```

Update the attributes of an [Entity](#).

#### Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target [Entity](#).
- **attribute** – Name of the attribute to get updated.

```
classmethod write_array_attribute(file: str | h5py.File, entity, attribute, values=None, **kwargs) → None
```

Add surveys of an object.

#### Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.
- **attribute** – Name of the attribute to be written to geoh5

```
classmethod write_attributes(file: str | h5py.File, entity) → None
```

Write attributes of an [Entity](#).

#### Parameters

- **file** – Name or handle to a geoh5 file.
- **entity** – Entity with attributes to be added to the geoh5 file.

```
classmethod write_color_map(file: str | h5py.File, entity_type: shared.EntityType) → None
```

Add [ColorMap](#) to a [DataType](#).

#### Parameters

- **file** – Name or handle to a geoh5 file
- **entity\_type** – Target entity\_type with color\_map

**classmethod** `write_data_values(file: str | h5py.File, entity, attribute, values=None, **kwargs)` → None  
Add data `values`.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity** – Target entity.
- **attribute** – Name of the attribute to be written to geoh5

**classmethod** `write_entity(file: str | h5py.File, entity)` → h5py.Group

Add an `Entity` and its attributes to geoh5. The function returns a pointer to the entity if already present on file.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity** – Target `Entity`.

**Return entity**

Pointer to the written entity. Active link if “close\_file” is False.

**classmethod** `write_entity_type(file: str | h5py.File, entity_type: shared.EntityType)` → h5py.Group

Add an `EntityType` to geoh5.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity\_type** – Entity with type to be added.

**Return type**

Pointer to `EntityType` in geoh5.

**classmethod** `write_file_name_data(entity_handle: Group, entity: FilenameData, values: bytes)` → None

Write a dataset for the file name and file blob.

**Parameters**

- **entity\_handle** – Pointer to the geoh5 Group.
- **entity** – Target `FilenameData` entity.
- **values** – Bytes data

**classmethod** `write_properties(file: str | h5py.File, entity: Entity)` → None

Add properties of an `Entity`.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity** – Target `Entity`.

**classmethod** `write_property_groups(file: str | h5py.File, entity)` → None

Write `PropertyGroup` associated with an `Entity`.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **entity** – Target `Entity`.

**classmethod** `write_to_parent(file: str | h5py.File, entity: Entity, recursively=False)` → None

Add/create an `Entity` and add it to its parent.

#### Parameters

- `file` – Name or handle to a geoh5 file.
- `entity` – Entity to be added or linked to a parent in geoh5.
- `recursively` – Add parents recursively until reaching the `RootGroup`.

**classmethod** `write_value_map(file: str | h5py.File, entity_type: shared.EntityType)` → None

Add `ReferenceValueMap` to a `DataType`.

#### Parameters

- `file` – Name or handle to a geoh5 file
- `entity_type` – Target entity\_type with value\_map

**classmethod** `write_visible(file: str | h5py.File, entity)` → None

Needs revision once Visualization is implemented

#### Parameters

- `file` – Name or handle to a geoh5 file
- `entity` – Target entity

## 2.3.4 geoh5py.objects

`geoh5py.objects.surveys`

`geoh5py.objects.surveys.electromagnetics`

`geoh5py.objects.surveys.electromagnetics.airborne_tem`

**class** `geoh5py.objects.surveys.electromagnetics.airborne_tem.AirborneTEMReceivers`(`object_type: Object-Type, **kwargs`)

Bases: `BaseAirborneTEM`

Airborne time-domain electromagnetic receivers class.

**property** `default_transmitter_type`

#### Returns

Transmitter class

**classmethod** `default_type_uid()` → UUID

#### Returns

Default unique identifier

**property** `type`

Survey element type

```
class geoh5py.objects.surveys.electromagnetics.airborne_tem.AirborneTEMTransmitters(object_type:  
    Ob-  
    ject-  
    Type,  
    **kwargs)
```

Bases: *BaseAirborneTEM*

Airborne time-domain electromagnetic transmitters class.

**property default\_receiver\_type**

**Returns**

Transmitter class

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property type**

Survey element type

```
class geoh5py.objects.surveys.electromagnetics.airborne_tem.BaseAirborneTEM(object_type:  
    ObjectType,  
    **kwargs)
```

Bases: *BaseEMSurvey*, *Curve*

**property crossline\_offset: float | uuid.UUID | None**

Numeric value or property UUID for the crossline offset between receiver and transmitter.

**property default\_input\_types: list[str]**

Input types. Must be one of ‘Rx’, ‘Tx’, ‘Tx and Rx’.

**property default\_metadata: dict**

Default dictionary of metadata for AirborneTEM entities.

**property default\_units: list[str]**

Accepted time units. Must be one of “Seconds (s)”, “Milliseconds (ms)”, “Microseconds (us)” or “Nanoseconds (ns)”

**fetch\_metadata(key: str) → float | uuid.UUID | None**

Fetch entry from the metadata.

**property inline\_offset: float | uuid.UUID | None**

Numeric value or property UUID for the inline offset between receiver and transmitter.

**property loop\_radius: float | None**

Transmitter loop radius

**property pitch: float | uuid.UUID | None**

Numeric value or property UUID for the pitch angle of the transmitter loop.

**property relative\_to\_bearing: bool | None**

Data relative\_to\_bearing

**property roll: float | uuid.UUID | None**

Numeric value or property UUID for the roll angle of the transmitter loop.

```
set_metadata(key: str, value: float | uuid.UUID | None)
```

**property timing\_mark: float | None**

Timing mark from the beginning of the discrete `waveform`. Generally used as the reference (time=0.0) for the provided (-) on-time an (+) off-time channels.

**property vertical\_offset: float | uuid.UUID | None**

Numeric value or property UUID for the vertical offset between receiver and transmitter.

**property waveform: np.ndarray | None**

Discrete waveform of the TEM source provided as `numpy.array` of type `float`, shape(n, 2)

```
waveform = [
    [time_1, current_1],
    [time_2, current_2],
    ...
]
```

**property yaw: float | uuid.UUID | None**

Numeric value or property UUID for the yaw angle of the transmitter loop.

## geoh5py.objects.surveys.electromagnetics.base

```
class geoh5py.objects.surveys.electromagnetics.base.BaseEMSurvey(object_type: ObjectType, **kwargs)
```

Bases: `ObjectBase`

A base electromagnetics survey object.

**add\_components\_data(data: dict) → list[PropertyGroup]**

Add lists of data components to an EM survey. The name of each component is appended to the metadata ‘Property groups’.

Data channels must be provided for every frequency or time in order specified by `channels`. The data channels can be supplied as either a list of `geoh5py.data.float_data.FloatData` entities or `uuid.UUID`

```
data = {
    "Component A": [
        data_entity_1,
        data_entity_2,
    ],
    "Component B": [...],
},
```

or a nested dictionary of arguments defining new Data entities as defined by the `add_data()` method.

```
data = {
    "Component A": {
        "time_1": {
            "values": [v_11, v_12, ...],
            "entity_type": entity_type_A,
        },
        ...
    },
}
```

(continues on next page)

(continued from previous page)

```
        time_2: {...},  
        ...,  
    },  
    "Component B": {...},  
}
```

**Parameters**

**data** – Dictionary of data components to be added to the survey.

**Returns**

List of property groups for all components added.

**add\_validate\_component\_data**(name: str, data\_block: list | dict)

Append a property group to the entity and its metadata after validations.

**property channels**

List of measured channels.

**property components: dict | None**

Rapid access to the list of data entities for all components.

**copy**(parent=None, copy\_children: bool = True) → BaseEMSurvey

Function to copy a AirborneTEMReceivers to a different parent entity.

**Parameters**

- **parent** – Target parent to copy the entity under. Copied to current **parent** if None.
- **copy\_children** – Create copies of AirborneTEMReceivers along with it.

**Return entity**

Registered AirborneTEMReceivers to the workspace.

**property default\_input\_types: list[str] | None**

Input types. Must be one of ‘Rx’, ‘Tx’, ‘Tx and Rx’.

**property default\_metadata**

Default metadata structure. Implemented on the child class.

**property default\_receiver\_type: type**

**Returns**

Receivers implemented on the child class.

**property default\_transmitter\_type: type**

**Returns**

Transmitters implemented on the child class.

**classmethod default\_type\_uid()** → UUID

Default unique identifier. Implemented on the child class.

**property default\_units: list[str] | None**

Accepted sampling units.

```
edit_metadata(entries: dict[str, Any])
```

Utility function to edit or add metadata fields and trigger an update on the receiver and transmitter entities.

**Parameters**

**entries** – Metadata key value pairs.

**property input\_type: str | None**

Data input type. Must be one of ‘Rx’, ‘Tx’ or ‘Tx and Rx’

**property metadata**

Metadata attached to the entity.

**property receivers: BaseEMSurvey | None**

The associated TEM receivers.

**property survey\_type: str | None**

Data input type. Must be one of ‘Rx’, ‘Tx’ or ‘Tx and Rx’

**property transmitters: BaseEMSurvey | None**

The associated TEM transmitters (sources).

**property type**

Survey element type

**property unit: float | None**

Default channel units for time or frequency defined on the child class.

## geoh5py.objects.surveys.electromagnetics.magnetotellurics

```
class geoh5py.objects.surveys.electromagnetics.magnetotellurics.MTReceivers(object_type:  
Object_Type,  
**kwargs)
```

Bases: *BaseEMSurvey, Points*

A magnetotellurics survey object.

**property default\_input\_types: list[str]**

Input types. Must be ‘Rx only’

**property default\_metadata: dict**

**Returns**

Default unique identifier

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property default\_units: list[str]**

Accepted time units. Must be one of “Seconds (s)”, “Milliseconds (ms)”, “Microseconds (us)” or “Nanoseconds (ns)”

**property type**

Survey element type

`geoh5py.objects.surveys.electromagnetics.tipper`

```
class geoh5py.objects.surveys.electromagnetics.tipper.BaseTipper(object_type: ObjectType,
                                                               base_stations:
                                                               TipperBaseStations | None =
                                                               None, **kwargs)
```

Bases: `BaseEMSurvey`

Base tipper survey class.

**property base\_stations: `TipperBaseStations` | `None`**

The base station entity

**property default\_input\_types: `list[str]`**

Input types. Must be ‘Rx and base stations’

**property default\_metadata: `dict`**

**Returns**

Default unique identifier

**property default\_units: `list[str]`**

Accepted time units. Must be one of “Seconds (s)”, “Milliseconds (ms)”, “Microseconds (us)” or “Nanoseconds (ns)”

```
class geoh5py.objects.surveys.electromagnetics.tipper.TipperBaseStations(object_type:
                                                               ObjectType,
                                                               **kwargs)
```

Bases: `BaseTipper`, `Points`

A z-tipper EM survey object.

**property default\_receiver\_type**

**Returns**

Receiver class

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property type**

Survey element type

```
class geoh5py.objects.surveys.electromagnetics.tipper.TipperReceivers(object_type: ObjectType,
                                                               **kwargs)
```

Bases: `BaseTipper`, `Curve`

A z-tipper EM survey object.

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property type**

Survey element type

**geoh5py.objects.surveys.direct\_current**

```
class geoh5py.objects.surveys.direct_current.CurrentElectrode(object_type: ObjectType,
**kwargs)
```

Bases: *PotentialElectrode*

Ground direct current electrode (transmitter).

**add\_default\_ab\_cell\_id()**

Utility function to set ab\_cell\_id's based on curve cells.

**copy(parent=None, copy\_children: bool = True)**

Function to copy a survey to a different parent entity.

**Parameters**

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy\_children** – Create copies of all children entities along with it.

**Return entity**

Registered Entity to the workspace.

**property current\_electrodes**

The associated current electrode object (sources).

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property potential\_electrodes: PotentialElectrode | None**

The associated potential\_electrodes (receivers)

```
class geoh5py.objects.surveys.direct_current.PotentialElectrode(object_type: ObjectType,
**kwargs)
```

Bases: *Curve*

Ground potential electrode (receiver).

**property ab\_cell\_id: ReferencedData | None**

Reference data entity mapping cells to a unique current dipole.

**property ab\_map: dict | None**

Get the ReferenceData.value\_map of the ab\_value\_id

**copy(parent=None, copy\_children: bool = True)**

Function to copy a survey to a different parent entity.

**Parameters**

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy\_children** – Create copies of all children entities along with it.

**Return entity**

Registered Entity to the workspace.

**property current\_electrodes**

The associated current electrode object (sources).

```
classmethod default_type_uid() → UUID
```

**Returns**

Default unique identifier

**property metadata**

Metadata attached to the entity.

**property potential\_electrodes**

The associated potential\_electrodes (receivers)

## geoh5py.objects.surveys.magnetics

```
class geoh5py.objects.surveys.magnetics.AirborneMagnetics(object_type: ObjectType, **kwargs)
```

Bases: *Curve*

An airborne magnetic survey object.

**Warning:** Partially implemented.

```
classmethod default_type_uid() → UUID
```

**Returns**

Default unique identifier

## geoh5py.objects.block\_model

```
class geoh5py.objects.block_model.BlockModel(object_type: ObjectType, **kwargs)
```

Bases: *ObjectBase*

Rectilinear 3D tensor mesh defined by three perpendicular axes. Each axis is divided into discrete intervals that define the cell dimensions. Nodal coordinates are determined relative to the origin and the sign of cell delimiters. Negative and positive cell delimiters are accepted to denote relative offsets from the origin.

**property cell\_delimiters**

**property centroids**

`numpy.array, shape (n_cells, 3):` Cell center locations in world coordinates.

```
centroids = [
    [x_1, y_1, z_1],
    ...,
    [x_N, y_N, z_N]
]
```

```
classmethod default_type_uid() → UUID
```

**Returns**

Default unique identifier

**property n\_cells: int | None**

`int:` Total number of cells

**property origin: ndarray**

numpy.array of float, shape (3, ): Coordinates of the origin.

**property rotation: float**

float: Clockwise rotation angle (degree) about the vertical axis.

**property shape: tuple | None**

list of int, len (3, ): Number of cells along the u, v and z-axis

**property u\_cell\_delimiters: np.ndarray | None**

numpy.array of float: Nodal offsets along the u-axis relative to the origin.

**property u\_cells: np.ndarray | None**

numpy.array of float, shape (*shape* [0], ): Cell size along the u-axis.

**property v\_cell\_delimiters: np.ndarray | None**

numpy.array of float: Nodal offsets along the v-axis relative to the origin.

**property v\_cells: np.ndarray | None**

numpy.array of float, shape (*shape* [1], ): Cell size along the v-axis.

**property z\_cell\_delimiters: np.ndarray | None**

numpy.array of float: Nodal offsets along the z-axis relative to the origin (positive up).

**property z\_cells: np.ndarray | None**

numpy.array of float, shape (*shape* [2], ): Cell size along the z-axis

## geoh5py.objects.curve

**class geoh5py.objects.curve.Curve(*object\_type*: ObjectType, \*\*kwargs)**

Bases: *Points*

Curve object defined by a series of line segments (*cells*) connecting *vertices*.

**property cells: np.ndarray | None**

numpy.ndarray of int, shape (\*, 2): Array of indices defining segments connecting vertices. Defined based on *parts* if set by the user.

**property current\_line\_id**

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property parts**

numpy.array of int, shape (*n\_vertices*, 2): Group identifiers for vertices connected by line segments as defined by the *cells* property. The definition of the *cells* property get modified by the setting of parts.

**property unique\_parts**

list of int: Unique *parts* identifiers.

## geoh5py.objects.drape\_model

**class** geoh5py.objects.drape\_model.DrapeModel(*object\_type*: ObjectType, \*\**kwargs*)

Bases: *ObjectBase*

Drape (curtain) model object made up of layers and prisms.

### property centroids

numpy.array of float, shape (n\_cells, 3): Cell center locations in world coordinates.

```
centroids = [
    [x_1, y_1, z_1],
    ...,
    [x_N, y_N, z_N]
]
```

**classmethod** default\_type\_uid() → UUID

**property** layers: np.ndarray | None

layers

**property** n\_cells

int: Number of cells.

**property** prisms: np.ndarray | None

prisms

## geoh5py.objects.drillhole

**class** geoh5py.objects.drillhole.Drillhole(*object\_type*: ObjectType, \*\**kwargs*)

Bases: *Points*

Drillhole object class defined by

**Warning:** Not yet implemented.

**add\_data**(*data*: dict, *property\_group*: str = None, *collocation\_distance*=None) → Data | list[Data]

Create Data specific to the drillhole object from dictionary of name and arguments. A keyword ‘depth’ or ‘from-to’ with corresponding depth values is expected in order to locate the data along the well path.

### Parameters

**data** – Dictionary of data to be added to the object, e.g.

```
data_dict = {
    "data_A": {
        'values', [v_1, v_2, ...],
        "from-to": numpy.ndarray,
    },
    "data_B": {
        'values', [v_1, v_2, ...],
        "depth": numpy.ndarray,
    },
}
```

**Parameters**

**property\_group** – Name of the property group to add the data into.

**Returns**

List of new Data objects.

**add\_vertices(*xyz*)**

Function to add vertices to the drillhole

**property cells: np.ndarray | None**

numpy.ndarray of int, shape (\*, 2): Array of indices defining segments connecting vertices.

**property collar**

numpy.array of float, shape (3, ): Coordinates of the collar

**property cost**

float: Cost estimate of the drillhole

**property default\_collocation\_distance**

Minimum collocation distance for matching depth on merge

**classmethod default\_type\_uid() → UUID**

**property depths: *FloatData* | None**

**desurvey(*depths*)**

Function to return x, y, z coordinates from depth.

**property end\_of\_hole: float | None**

End of drillhole in meters

**property from\_**

Depth data corresponding to the tops of the interval values.

**property locations: np.ndarray | None**

Lookup array of the well path in x, y, z coordinates.

**property planning: str**

Status of the hole on of “Default”, “Ongoing”, “Planned”, “Completed” or “No status”

**sort\_depths()**

Read the ‘DEPTH’ data and sort all Data.values if needed

**property surveys: np.ndarray | None**

Coordinates of the surveys

**property to\_**

Depth data corresponding to the bottoms of the interval values.

**property trace: np.ndarray | None**

numpy.array: Drillhole trace defining the path in 3D

**property trace\_depth: np.ndarray | None**

numpy.array: Drillhole trace depth from top to bottom

**validate\_data(*attributes: dict, property\_group=None, collocation\_distance=None*) → tuple**

Validate input drillhole data attributes.

**Parameters**

- **attributes** – Dictionary of data attributes.
- **property\_group** – Input property group to validate against.

**validate\_interval\_data**(*from\_to*: *np.ndarray* | *list*, *values*: *np.ndarray*, *collocation\_distance*: *float* = 0.0001)

Compare new and current depth values, append new vertices if necessary and return an augmented values vector that matches the vertices indexing.

**validate\_log\_data**(*depth*: *ndarray*, *input\_values*: *ndarray*, *collocation\_distance*=0.0001) → *ndarray*

Compare new and current depth values. Append new vertices if necessary and return an augmented values vector that matches the vertices indexing.

**geoh5py.objects.drillhole.compute\_deviation**(*surveys*: *np.ndarray*, *axis*: *str*) → *np.ndarray* | *None*

Compute deviation from survey parameters

## geoh5py.objects.geo\_image

**class** geoh5py.objects.geo\_image.**GeoImage**(*object\_type*: *ObjectType*, *\*\*kwargs*)

Bases: *ObjectBase*

Image object class.

**Warning:** Not yet implemented.

**property cells: np.ndarray | None**

*numpy.ndarray* of *int*, shape (\*, 2): Array of indices defining segments connecting vertices. Defined based on *parts* if set by the user.

**classmethod default\_type\_uid()** → *UUID*

**property default\_vertices**

Assign the default vertices based on image pixel count

**georeference**(*reference*: *np.ndarray* | *list*, *locations*: *np.ndarray* | *list*)

Georeference the image vertices (corners) based on input reference and corresponding world coordinates.

### Parameters

- **reference** – Array of integers representing the reference used as reference points.
- **locations** – Array of floats for the corresponding world coordinates for each input pixel.

### Return vertices

Corners (vertices) in world coordinates.

**property image**

Get the image as a *PIL.Image* object.

**property image\_data**

Get the *FilenameData* entity holding the image.

**property vertices: np.ndarray | None**

*vertices*: Defines the four corners of the geo\_image

**geoh5py.objects.grid2d**

```
class geoh5py.objects.grid2d.Grid2D(object_type: ObjectType, **kwargs)
```

Bases: *ObjectBase*

Rectilinear 2D grid of uniform cell size. The grid can be oriented in 3D space through horizontal *rotation* and *dip* parameters. Nodal coordinates are determined relative to the origin and the sign of cell delimiters.

**property cell\_center\_u: np.ndarray | None**

numpy.array of float, shape(*u\_count*, ): Cell center local coordinate along the u-axis.

**property cell\_center\_v: np.ndarray | None**

numpy.array of float shape(*u\_count*, ): The cell center local coordinate along the v-axis.

**property centroids: np.ndarray | None**

numpy.array of float, shape (*n\_cells*, 3): Cell center locations in world coordinates.

```
centroids = [
    [x_1, y_1, z_1],
    ...,
    [x_N, y_N, z_N]
]
```

**classmethod default\_type\_uid() → UUID**

**Returns**

Default unique identifier

**property dip: float**

float: Dip angle from horizontal (positive down) in degrees.

**property n\_cells: int | None**

int: Total number of cells.

**property origin: ndarray**

numpy.array of float, shape (3, ): Coordinates of the origin.

**property rotation: float**

float: Clockwise rotation angle (degree) about the vertical axis.

**property shape: tuple | None**

list of int, len (2, ): Number of cells along the u and v-axis.

**property u\_cell\_size: float | None**

float: Cell size along the u-axis.

**property u\_count: int | None**

int: Number of cells along u-axis

**property v\_cell\_size: float | None**

float: Cell size along the v-axis

**property v\_count: int | None**

int: Number of cells along v-axis

**property vertical: bool | None**

bool: Set the grid to be vertical.

## geoh5py.objects.integrator

```
class geoh5py.objects.integrator.IntegratorPoints(object_type: ObjectType, **kwargs)
```

Bases: *Points*

INTEGRATOR Points object. Sub-class of *geoh5py.objects.points.Points*.

```
classmethod default_type_uid() → UUID
```

```
class geoh5py.objects.integrator.NeighbourhoodSurface(object_type: ObjectType, **kwargs)
```

Bases: *Surface*

Points object made up of vertices.

```
classmethod default_type_uid() → UUID
```

## geoh5py.objects.label

```
class geoh5py.objects.label.Label(object_type: ObjectType, **kwargs)
```

Bases: *ObjectBase*

Label object for annotation in viewport.

**Warning:** Not yet implemented.

```
classmethod default_type_uid() → UUID
```

## geoh5py.objects.notype\_object

```
class geoh5py.objects.notype_object.NoTypeObject(object_type: ObjectType, **kwargs)
```

Bases: *ObjectBase*

Generic Data object without a registered type

```
classmethod default_type_uid() → UUID
```

## geoh5py.objects.object\_base

```
class geoh5py.objects.object_base.ObjectBase(object_type: ObjectType, **kwargs)
```

Bases: *Entity*

Object base class.

```
add_comment(comment: str, author: Optional[str] = None)
```

Add text comment to an object.

### Parameters

- **comment** – Text to be added as comment.
- **author** – Name of author or defaults to *contributors*.

**add\_data**(*data: dict, property\_group: str = None*) → *Data | list[Data]*

Create *Data* from dictionary of name and arguments. The provided arguments can be any property of the target Data class.

#### Parameters

**data** – Dictionary of data to be added to the object, e.g.

```
data = {
    "data_A": {
        'values': [v_1, v_2, ...],
        'association': 'VERTEX'
    },
    "data_B": {
        'values': [v_1, v_2, ...],
        'association': 'CELLS'
    },
}
```

#### Returns

List of new Data objects.

**add\_data\_to\_group**(*data: list | Data | uuid.UUID, name: str*) → *PropertyGroup*

Append data children to a *PropertyGroup* All given data must be children of the parent object.

#### Parameters

- **data** – *Data* object, *uid* or *name* of data.
- **name** – Name of a *PropertyGroup*. A new group is created if none exist with the given name.

#### Returns

The target property group.

### property cells

`numpy.array of int`: Array of indices defining the connection between *vertices*.

### property comments

Fetch a *CommentsData* entity from children.

### abstract classmethod default\_type\_uid() → UUID

### property entity\_type: ObjectType

*EntityType*: Object type.

### property faces

### find\_or\_create\_property\_group(\*\*kwargs) → PropertyGroup

Find or create *PropertyGroup* from given name and properties.

#### Parameters

**kwargs** – Any arguments taken by the *PropertyGroup* class.

#### Returns

A new or existing *PropertyGroup*

**classmethod** **find\_or\_create\_type**(*workspace*: workspace.Workspace, \*\**kwargs*) → *ObjectType*

Find or create a type instance for a given object class.

**Parameters**

**workspace** – Target *Workspace*.

**Returns**

The *ObjectType* instance for the given object class.

**get\_data**(*name*: str | uuid.UUID) → list[*Data*]

Get a child *Data* by name.

**Parameters**

**name** – Name of the target child data

**Returns**

A list of children *Data* objects

**get\_data\_list**(*attribute*=‘name’) → list[str]

Get a list of names of all children *Data*.

**Returns**

List of names of data associated with the object.

**property** **last\_focus**: str

bool: Object visible in camera on start.

**property** **n\_cells**: int | None

int: Number of cells.

**property** **n\_vertices**: int | None

int: Number of vertices.

**property** **property\_groups**: list[*PropertyGroup*] | None

list of *PropertyGroup*.

**validate\_data\_association**(*attribute\_dict*)

Get a dictionary of attributes and validate the data ‘association’ keyword.

**static** **validate\_data\_type**(*attribute\_dict*)

Get a dictionary of attributes and validate the type of data.

**property** **vertices**

numpy.array of float, shape (\*, 3): Array of x, y, z coordinates defining the position of points in 3D space.

## geoh5py.objects.object\_type

**class** geoh5py.objects.object\_type.**ObjectType**(*workspace*: workspace.Workspace, \*\**kwargs*)

Bases: *EntityType*

Object type class

**static** **create\_custom**(*workspace*: workspace.Workspace) → *ObjectType*

Creates a new instance of *ObjectType* for an unlisted custom Object type with a new auto-generated UUID.

**Parameters**

**workspace** – An active *Workspace* class

---

**classmethod** `find_or_create(workspace: workspace.Workspace, entity_class, **kwargs) → ObjectType`

Find or creates an EntityType with given `uuid.UUID` that matches the given Group implementation class.

It is expected to have a single instance of EntityType in the Workspace for each concrete Entity class.

#### Parameters

- `workspace` – An active Workspace class
- `entity_class` – An Group implementation class.

#### Returns

A new instance of GroupType.

## geoh5py.objects.octree

**class** `geoh5py.objects.octree.Octree(object_type: ObjectType, **kwargs)`

Bases: `ObjectBase`

Octree mesh class that uses a tree structure such that cells can be subdivided it into eight octants.

#### `base_refine()`

Refine the mesh to its base octree level resulting in a single cell along the shortest dimension.

#### `property centroids`

`numpy.array of float, shape (n_cells, 3):` Cell center locations in world coordinates.

```
centroids = [
    [x_1, y_1, z_1],
    ...,
    [x_N, y_N, z_N]
]
```

#### `classmethod default_type_uid() → UUID`

#### `property n_cells: int | None`

`int:` Total number of cells in the mesh

#### `property octree_cells: np.ndarray | None`

`numpy.ndarray of int, shape (n_cells, 4):` Array defining the i, j, k position and size of each cell. The size defines the width of a cell in number of base cells.

```
cells = [
    [i_1, j_1, k_1, size_1],
    ...,
    [i_N, j_N, k_N, size_N]
]
```

#### `property origin`

`numpy.array of float, shape (3, ):` Coordinates of the origin

#### `property rotation: float`

`float:` Clockwise rotation angle (degree) about the vertical axis.

#### `property shape: tuple | None`

`list of int, len (3, ):` Number of cells along the u, v and w-axis.

```
property u_cell_size: float | None
    float: Base cell size along the u-axis.

property u_count: int | None
    int: Number of cells along u-axis.

property v_cell_size: float | None
    float: Base cell size along the v-axis.

property v_count: int | None
    int: Number of cells along v-axis.

property w_cell_size: float | None
    float: Base cell size along the w-axis.

property w_count: int | None
    int: Number of cells along w-axis.
```

## geoh5py.objects.points

```
class geoh5py.objects.Points(object_type: ObjectType, **kwargs)
    Bases: ObjectBase

    Points object made up of vertices.

    classmethod default_type_uid() → UUID

    property vertices: np.ndarray | None
        vertices
```

## geoh5py.objects.surface

```
class geoh5py.objects.Surface(object_type: ObjectType, **kwargs)
    Bases: Points

    Surface object defined by vertices and cells

    property cells: np.ndarray | None
        Array of vertices index forming triangles :return cells: numpy.array of int, shape ("*", 3)

    classmethod default_type_uid() → UUID
```

## 2.3.5 geoh5py.shared

### geoh5py.shared.concatenation

```
class geoh5py.shared.concatenation.Concatenated(entity_type, **kwargs)
    Bases: Entity

    Base class modifier for concatenated objects and data.

    property concatenator: Concatenator
        Parental Concatenator entity.
```

```
class geoh5py.shared.concatenation.ConcatenatedData(entity_type, **kwargs)
```

Bases: *Concatenated*

**property parent:** *Concatenated*

**property property\_group**

Get the property group containing the data interval.

```
class geoh5py.shared.concatenation.ConcatenatedDrillhole(entity_type, **kwargs)
```

Bases: *ConcatenatedObject*

**property from\_:** list[*Data*]

Depth data corresponding to the tops of the interval values.

**sort\_depths()**

Bypass sort\_depths from previous version.

**property to\_:** list[*Data*]

Depth data corresponding to the bottoms of the interval values.

**validate\_data**(*attributes*: dict, *property\_group*=None, *collocation\_distance*=None) → tuple

Validate input drillhole data attributes.

#### Parameters

- **attributes** – Dictionary of data attributes.
- **property\_group** – Input property group to validate against.

**validate\_interval\_data**(*name*: str | None, *from\_to*: list | np.ndarray | None, *values*: np.ndarray, *group\_name*: str = None, *collocation\_distance*=0.0001) → str

Compare new and current depth values and re-use the property group if possible. Otherwise a new property group is added.

#### Parameters

- **from\_to** – Array of from-to values.
- **values** – Data values to be added on the from-to intervals.
- **group\_name** – Property group name

#### Collocation\_distance

Threshold on the comparison between existing depth values.

```
class geoh5py.shared.concatenation.ConcatenatedObject(entity_type, **kwargs)
```

Bases: *Concatenated*

**get\_data**(*name*: str | uuid.UUID) → list[*Data*]

Generic function to get data values from object.

**get\_data\_list()**

Get list of data names.

**property parent:** *Concatenator*

**property property\_groups:** list | None

```
class geoh5py.shared.concatenation.ConcatenatedPropertyGroup(**kwargs)
```

Bases: *PropertyGroup*

**property from\_**

Return the data entities definind the ‘from’ depth intervals.

**property parent: Concatenated**

The parent *ObjectBase*

**property to\_**

Return the data entities definind the ‘to’ depth intervals.

**class** geoh5py.shared.concatenation.Concatenator(*group\_type*: GroupType, \*\**kwargs*)

Bases: *Group*

Class modifier for concatenation of objects and data.

**add\_save\_concatenated(*child*) → None**

Add or save a concatenated entity.

**Parameters**

**child** – Concatenated entity

**property attributes\_keys: list | None**

List of uuids present in the concatenated attributes.

**property concatenated\_attributes: dict | None**

Dictionary of concatenated objects and data attributes.

**property concatenated\_object\_ids: list[bytes] | None**

Dictionary of concatenated objects and data concatenated\_object\_ids.

**copy(*parent=None*, *copy\_children: bool = True*)**

Function to copy an entity to a different parent entity.

**Parameters**

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy\_children** – Create copies of all children entities along with it.

**Return entity**

Registered Entity to the workspace.

**property data: dict**

Concatenated data values stored as a dictionary.

**delete\_index\_data(*label: str*, *index: int*) → None**

**fetch\_concatenated\_data\_index()**

Extract concatenation arrays.

**fetch\_concatenated\_objects() → dict**

Load all concatenated children.

**fetch\_index(*entity: Concatenated*, *field: str*) → int | None**

Fetch the array index for specific concatenated object and data field.

**Parameters**

- **entity** – Parent entity with data
- **field** – Name of the target data.

**fetch\_start\_index**(entity: Concatenated, label: str) → int

Fetch starting index for a given entity and label. Existing date is removed such that new entries can be appended.

**Parameters**

- **entity** – Concatenated entity to be added.
- **label** – Name of the attribute requiring an update.

**fetch\_values**(entity: Concatenated, field: str) → np.ndarray | None

Get an array of values from concatenated data.

**Parameters**

- **entity** – Parent entity with data
- **field** – Name of the target data.

**get\_attributes**(uid: bytes | str | uuid.UUID) → dict

Fast reference index to concatenated attribute keys.

**property index: dict**

Concatenated index stored as a dictionary.

**property property\_group\_ids: list | None**

Dictionary of concatenated objects and data property\_group\_ids.

**remove\_entity**(entity: Concatenated)

Remove a concatenated entity.

**save\_attribute**(field: str)

Save a concatenated attribute.

**Parameters**

- **field** – Name of the attribute

**update\_array\_attribute**(entity: Concatenated, field: str, remove=False) → None

Update values stored as data. Row data and indices are first remove then appended.

**Parameters**

- **entity** – Concatenated entity with array values.
- **field** – Name of the valued field.

**update\_attributes**(entity: Concatenated, label: str) → None

Update a concatenated entity.

**update\_concatenated\_attributes**(entity: Concatenated) → None

Update the concatenated attributes. :param entity: Concatenated entity with attributes.

## geoh5py.shared.entity

**class** geoh5py.shared.entity.Entity(*uid: uuid.UUID | None = None, \*\*kwargs*)

Bases: ABC

Base Entity class

**add\_children**(*children: list[shared.Entity]*)

### Parameters

**children** – Add a list of entities as *children*

**add\_file**(*file: str*)

Add a file to the object or group stored as bytes on a FilenameData

### Parameters

**file** – File name with path to import.

**property allow\_delete: bool**

bool Entity can be deleted from the workspace.

**property allow\_move: bool**

bool Entity can change *parent*

**property allow\_rename: bool**

bool Entity can change name

**property attribute\_map: dict**

dict Correspondence map between property names used in geoh5py and geoh5.

**property children**

list Children entities in the workspace tree

**property clipping\_ids: list[uuid.UUID] | None**

List of clipping uuids

**copy**(*parent=None, copy\_children: bool = True*)

Function to copy an entity to a different parent entity.

### Parameters

- **parent** – Target parent to copy the entity under. Copied to current *parent* if None.
- **copy\_children** – Create copies of all children entities along with it.

### Return entity

Registered Entity to the workspace.

**classmethod create**(*workspace, \*\*kwargs*)

Function to create an entity.

### Parameters

- **workspace** – Workspace to be added to.
- **kwargs** – List of keyword arguments defining the properties of a class.

### Return entity

Registered Entity to the workspace.

**abstract property entity\_type: shared.EntityType**

**classmethod** `fix_up_name(name: str) → str`

If the given name is not a valid one, transforms it to make it valid :return: a valid name built from the given name. It simply returns the given name if it was already valid.

**get\_entity(name: str | uuid.UUID) → list[*Entity*]**

Get a child *Data* by name.

**Parameters**

- **name** – Name of the target child data
- **entity\_type** – Sub-select entities based on type.

**Returns**

A list of children Data objects

**get\_entity\_list(entity\_type=<class 'abc.ABC'>) → list[str]**

Get a list of names of all children *Data*.

**Parameters**

- **entity\_type** – Option to sub-select based on type.

**Returns**

List of names of data associated with the object.

**property metadata: dict | None**

Metadata attached to the entity.

**property name: str**

str Name of the entity

**property on\_file: bool**

Whether this Entity is already stored on *h5file*.

**property parent**

**property partially\_hidden: bool**

Whether this Entity is partially hidden.

**property public: bool**

**Whether this Entity is accessible in the workspace tree and other parts**

of the the user interface in ANALYST.

**reference\_to\_uid(value: Entity | str | uuid.UUID) → list[uuid.UUID]**

General entity reference translation.

**Parameters**

- **value** – Either an *Entity*, string or uid

**Returns**

List of unique identifier associated with the input reference.

**remove\_children(children: list[shared.Entity])**

Remove children from the list of children entities.

**Parameters**

- **children** – List of entities

**Warning:** Removing a child entity without re-assigning it to a different parent may cause it to become inactive. Inactive entities are removed from the workspace by `remove_none_referents()`.

**remove\_data\_from\_group**(*data*: list | Entity | `uuid.UUID` | str, *name*: str = `None`) → None

Remove data children to a *PropertyGroup* All given data must be children of the parent object.

#### Parameters

- **data** – *Data* object, `uid` or `name` of data.
- **name** – Name of a *PropertyGroup*. A new group is created if none exist with the given name.

**save**(*add\_children*: bool = `True`)

Alias method of `save_entity()`.

#### Parameters

**add\_children** – Option to also save the children.

**property uid: UUID**

**property visible: bool**

Whether the Entity is visible in camera (checked in ANALYST object tree).

**property workspace: Workspace**

*Workspace* to which the Entity belongs to.

## geoh5py.shared.entity\_type

**class geoh5py.shared.entity\_type.EntityType**(*workspace*: ws.Workspace, *uid*: `uuid.UUID` | `None` = `None`, \*\**kwargs*)

Bases: ABC

**property attribute\_map**

dict Correspondence map between property names used in geoh5py and geoh5.

**property description: str | None**

**classmethod find**(*workspace*: ws.Workspace, *type\_uid*: `uuid.UUID`) → EntityTypeT | `None`

Finds in the given Workspace the EntityType with the given UUID for this specific EntityType implementation class.

#### Returns

EntityType of `None`

**property name: str | None**

**property on\_file: bool**

bool Entity already present in *h5file*.

**property uid: UUID**

`uuid.UUID` The unique identifier of an entity, either as stored in geoh5 or generated in `uuid4()` format.

**property workspace: ws.Workspace**

*Workspace* registering this type.

## geoh5py.shared.exceptions

```
exception geoh5py.shared.exceptions.AssociationValidationError(name: str, value: Entity |  
                                         PropertyGroup | UUID,  
                                         validation: Entity | Workspace)
```

Bases: *BaseValidationError*

Error on association between child and parent entity validation.

```
static message(name, value, validation)
```

Builds custom error message.

```
exception geoh5py.shared.exceptions.AtLeastOneValidationException(name: str, value: list[str])
```

Bases: *BaseValidationError*

```
static message(name, value, validation=None)
```

Builds custom error message.

```
exception geoh5py.shared.exceptions.BaseValidationException
```

Bases: ABC, Exception

Base class for custom exceptions.

```
abstract static message(name, value, validation)
```

Builds custom error message.

```
exception geoh5py.shared.exceptions.Geoh5FileClosedException
```

Bases: ABC, Exception

Error for closed geoh5 file.

```
exception geoh5py.shared.exceptions.JSONParameterValidationException(name: str, err: str)
```

Bases: Exception

Error on uuid validation.

```
static message(name, err)
```

```
exception geoh5py.shared.exceptions.OptionalValidationException(name: str, value: Any | None,  
                                                               validation: bool)
```

Bases: *BaseValidationException*

Error if None value provided to non-optional parameter.

```
static message(name, value, validation)
```

Builds custom error message.

```
exception geoh5py.shared.exceptions.PropertyGroupValidationException(name: str, value:  
                                                               PropertyGroup, validation: str)
```

Bases: *BaseValidationException*

Error on property group validation.

```
static message(name, value, validation)
```

Builds custom error message.

```
exception geoh5py.shared.exceptions.RequiredValidationException(name: str)
```

Bases: *BaseValidationException*

**static message**(name, value=None, validation=None)

Builds custom error message.

**exception** geoh5py.shared.exceptions.ShapeValidationException(name: str, value: tuple[int], validation: tuple[int] | str)

Bases: *BaseValidationError*

Error on shape validation.

**static message**(name, value, validation)

Builds custom error message.

**exception** geoh5py.shared.exceptions.TypeValidationException(name: str, value: str, validation: str | list[str])

Bases: *BaseValidationError*

Error on type validation.

**static message**(name, value, validation)

Builds custom error message.

**exception** geoh5py.shared.exceptions.UUIDValidationException(name: str, value: str)

Bases: *BaseValidationError*

Error on uuid string validation.

**static message**(name, value, validation=None)

Builds custom error message.

**exception** geoh5py.shared.exceptions.ValueValidationException(name: str, value: Any, validation: list[Any])

Bases: *BaseValidationError*

Error on value validation.

**static message**(name, value, validation)

Builds custom error message.

## geoh5py.shared.utils

geoh5py.shared.utils.as\_str\_if\_utf8\_bytes(value) → str

Convert bytes to string

geoh5py.shared.utils.as\_str\_if\_uuid(value: UUID | Any) → str | Any

Convert UUID to string used in geoh5.

geoh5py.shared.utils.bool\_value(value: int8) → bool

Convert logical int8 to bool.

geoh5py.shared.utils.compare\_entities(object\_a, object\_b, ignore: list | None = None, decimal: int = 6)  
→ None

geoh5py.shared.utils.dict\_mapper(val, string\_funcs: list[Callable], \*args, omit: dict | None = None) → dict

Recursion through nested dictionaries and applies mapping functions to values.

### Parameters

- **val** – Value (could be another dictionary) to apply transform functions.

- **string\_funcs** – Functions to apply on values within the input dictionary.
- **omit** – Dictionary of functions to omit.

**Return val**

Transformed values

`geoh5py.shared.utils.entity2uuid(value: Any) → UUID | Any`

Convert an entity to its UUID.

`geoh5py.shared.utils.fetch_h5_handle(file: str | h5py.File | Path, mode: str = 'r') → h5py.File`

Open in read+ mode a geoh5 file from string. If receiving a file instead of a string, merely return the given file.

**Parameters**

- **file** – Name or handle to a geoh5 file.
- **mode** – Set the h5 read/write mode

**Return h5py.File**

Handle to an opened h5py file.

`geoh5py.shared.utils.get_attributes(entity: Entity | EntityType, omit_list=(), attributes=None)`

Extract the attributes of an object with omissions.

`geoh5py.shared.utils.is_uuid(value: str) → bool`

Check if a string is UUID compliant.

`geoh5py.shared.utils.iteratorable(value: Any, checklen: bool = False) → bool`

Checks if object is iterable.

**Parameters****value**

[Object to check for iterability.]

**checklen**

[Restrict objects with \_\_iter\_\_ method to len > 1.]

**Returns**

**True if object has \_\_iter\_\_ attribute but is not string or dict type.**

`geoh5py.shared.utils.iteratorable_message(valid: list[Any] | None) → str`

Append possibly iterable valid: “Must be (one of): {valid}.”

`geoh5py.shared.utils.match_values(vec_a, vec_b, collocation_distance=0.0001) → ndarray`

Find indices of matching values between two arrays, within collocation\_distance.

**Param**

vec\_a, list or numpy.ndarray Input sorted values

**Param**

vec\_b, list or numpy.ndarray Query values

**Returns**

indices, numpy.ndarray Pairs of indices for matching values between the two arrays such that  
vec\_a[ind[:, 0]] == vec\_b[ind[:, 1]].

`geoh5py.shared.utils.merge_arrays(head, tail, replace='A->B', mapping=None, collocation_distance=0.0001, return_mapping=False) → ndarray`

Given two numpy.arrays of different length, find the matching values and append both arrays.

**Param**

head, numpy.array of float First vector of shape(M,) to be appended.

**Param**

tail, numpy.array of float Second vector of shape(N,) to be appended

**Param**

mapping=None, numpy.ndarray of int Optional array where values from the head are replaced by the tail.

**Param**

collocation\_distance=1e-4, float Tolerance between matching values.

**Returns**

numpy.array shape(O,) Unique values from head to tail without repeats, within collocation\_distance.

`geoh5py.shared.utils.str2uuid(value: Any) → UUID | Any`

Convert string to UUID

`geoh5py.shared.utils.uuid2entity(value: UUID, workspace: Workspace) → Entity | Any`

Convert UUID to a known entity.

## geoh5py.shared.validators

`class geoh5py.shared.validators.AssociationValidator(**kwargs)`

Bases: `BaseValidator`

Validate the association between data and parent object.

`classmethod validate(name: str, value: Entity | PropertyGroup | UUID | None, valid: Entity | Workspace) → None`

**Parameters**

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Expected value shape

`validator_type = 'association'`

`class geoh5py.shared.validators.AtLeastOneValidator(**kwargs)`

Bases: `BaseValidator`

`classmethod validate(name, value, valid)`

Custom validation function.

`validator_type = 'one_of'`

`class geoh5py.shared.validators.BaseValidator(**kwargs)`

Bases: ABC

Concrete base class for validators.

`abstract classmethod validate(name: str, value: Any, valid: Any)`

Custom validation function.

**abstract property validator\_type**

Validation type identifier.

```
class geoh5py.shared.validators.OptionalValidator(**kwargs)
```

Bases: *BaseValidator*

Validate that forms contain optional parameter if None value is given.

```
classmethod validate(name: str, value: Any | None, valid: bool) → None
```

**Parameters**

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – True if optional keyword in form for parameter.

```
validator_type = 'optional'
```

```
class geoh5py.shared.validators.PropertyGroupValidator(**kwargs)
```

Bases: *BaseValidator*

Validate property\_group from parent entity.

```
classmethod validate(name: str, value: PropertyGroup, valid: str) → None
```

Custom validation function.

```
validator_type = 'property_group_type'
```

```
class geoh5py.shared.validators.RequiredValidator(**kwargs)
```

Bases: *BaseValidator*

Validate that required keys are present in parameter.

```
classmethod validate(name: str, value: Any, valid: bool) → None
```

**Parameters**

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Assert to be required

```
validator_type = 'required'
```

```
class geoh5py.shared.validators.ShapeValidator(**kwargs)
```

Bases: *BaseValidator*

Validate the shape of provided value.

```
classmethod validate(name: str, value: Any, valid: tuple[int]) → None
```

**Parameters**

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – Expected value shape

```
validator_type = 'shape'
```

```
class geoh5py.shared.validators.TypeValidator(**kwargs)
Bases: BaseValidator

Validate the value type from a list of valid types.

classmethod validate(name: str, value: Any, valid: list[type] | type) → None
```

#### Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – List of accepted value types

**validator\_type = 'types'**

```
class geoh5py.shared.validators.UUIDValidator(**kwargs)
Bases: BaseValidator

Validate a uuuu.UUID value or uuid string.

classmethod validate(name: str, value: Any, valid: None = None) → None
```

#### Parameters

- **name** – Parameter identifier.
- **value** – Input parameter uuid.
- **valid** – [Optional] Validate uuid from parental entity or known uuids

**validator\_type = 'uuid'**

```
class geoh5py.shared.validators.ValueValidator(**kwargs)
Bases: BaseValidator

Validator that ensures that values are valid entries.

classmethod validate(name: str, value: Any, valid: list[float | str]) → None
```

#### Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **valid** – List of accepted values

**validator\_type = 'values'**

## geoh5py.shared.weakref\_utils

```
geoh5py.shared.weakref_utils.get_clean_ref(some_dict: dict[K, ReferenceType[T]], key: K) → T | None

Gets the referent value for the given key in a some_dict of weakref values. In case key points to a reference
to a deleted value, remove that key from some_dict on the fly, and returns None.
```

#### Parameters

- **some\_dict** – The dictionary of weakref values.
- **key** – The key

**Returns**

the referent value for key if found in the the dictionary, else None.

`geoh5py.shared.weakref_utils.insert_once(some_dict: dict[K, ReferenceType], key: K, value)`

Check if the reference to an Entity with uid is already in use.

**Parameters**

- **some\_dict** – Dictionary of UUID keys and weakref values.
- **key** – UUID key to be checked.
- **value** – Entity to be checked

**Returns**

Dictionary with clean weakref

`geoh5py.shared.weakref_utils.remove_none_referents(some_dict: dict[K, ReferenceType])`

Removes any key from the given `some_dict` where the value is a reference to a deleted value (that is where referent of the `weakref` value is `None`).

**Parameters**

`some_dict` – The dictionary to be cleaned up.

## 2.3.6 geoh5py.ui\_json

`geoh5py.ui_json.constants`

`geoh5py.ui_json.input_file`

`class geoh5py.ui_json.input_file.InputFile(data: dict[str, Any] = None, ui_json: dict[str, Any] = None, validations: dict = None, validation_options: dict = None)`

Bases: `object`

Handles loading ui.json input files.

**Attributes****data**

[Input file content parsed to flat dictionary of key:value.]

**ui\_json:** User interface serializable as ui.json format

**workspace:** Target

[obj:`geoh5py.workspace.Workspace`]

**validations:** Dictionary of validations for parameters in the input file

**Methods**

<code>write_ui_json()</code>	Writes a ui.json formatted file from ‘data’ attribute contents.
------------------------------	---

<code>read_ui_json()</code>	Reads a ui.json formatted file into ‘data’ attribute dictionary. Optionally filters ui.json fields other than ‘value’.
-----------------------------	--

`association_validator = <geoh5py.shared.validators.AssociationValidator object>`

`property data`

**load**(*input\_dict*: *dict[str, Any]*)

Load data from dictionary and validate.

**property name: str | None**

Name of ui.json file.

**classmethod numify**(*ui\_json*: *dict[str, Any]*) → *dict[str, Any]*

Convert inf, none and list strings to numerical types within a dictionary

#### Parameters

**ui\_json**

dictionary containing ui.json keys, values, fields

#### Returns

Dictionary with inf, none and list string representations converted numerical types.

**property path: str | None**

Directory for the input/output ui.json file.

**property path\_name: str | None**

**static read\_ui\_json**(*json\_file*: *str*, *\*\*kwargs*)

Read and create an InputFile from ui.json

**property ui\_json: dict | None**

Dictionary representing the ui.json file with promoted values.

**classmethod ui\_validation**(*ui\_json*: *dict[str, Any]*)

Validation of the ui\_json forms

**update\_ui\_values**(*data*: *dict*, *none\_map=None*)

Update the ui.json values and enabled status from input data.

#### Parameters

- **data** – Key and value pairs expected by the ui\_json.

- **none\_map** – Map parameter ‘None’ values to non-null numeric types. The parameters in the dictionary are mapped to optional and disabled.

#### Raises

**UserWarning** – If attempting to set None value to non-optional parameter.

**property validation\_options**

Pass validation options to the validators.

**property validations**

**property validators**

**property workspace**

**write\_ui\_json**(*name*: *str* = *None*, *none\_map*: *dict[str, Any]* = *None*, *path*: *str* = *None*)

Writes a formatted ui.json file from InputFile data

#### Parameters

- **name** – Name of the file

- **none\_map** – Map parameter None values to non-null numeric types.

- **path** – Directory to write the ui.json to.

## geoh5py.ui\_json.templates

`geoh5py.ui_json.templates.bool_parameter`(*main*: bool = True, *label*: str = 'Logical data', *value*: bool = False) → dict

Checkbox for true/false choice.

### Parameters

- **main** – Show ui in main.
- **label** – Label identifier.
- **value** – Input value.

### Returns

Ui\_json compliant dictionary.

`geoh5py.ui_json.templates.choice_string_parameter`(*main*: bool = True, *label*: str = 'String data', *choice\_list*: tuple = ('Option A', 'Option B'), *value*: str = 'Option A', *optional*: str | None = None) → dict

Dropdown menu of string choices.

### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **choice\_list** – List of options.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

`geoh5py.ui_json.templates.data_parameter`(*main*: bool = True, *label*: str = 'Data channel', *association*: str = 'Vertex', *data\_type*: str = 'Float', *data\_group\_type*: str = None, *parent*: str = "", *value*: str = "", *optional*: str | None = None) → dict

Dropdown menu of data from parental object.

### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **association** – Data association type from ‘Vertex’ or ‘Cell’.
- **data\_type** – Type of data selectable from ‘Float’, ‘Integer’ or ‘Reference’.
- **data\_group\_type** – [Optional] Select from property\_groups of type. ‘3D vector’, ‘Dip direction & dip’, ‘Strike & dip’, or ‘Multi-element’.
- **parent** – Parameter name corresponding to the parent object.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.data_value_parameter(main: bool = True, label: str = 'Data channel',  
                                              association: str = 'Vertex', data_type: str = 'Float',  
                                              parent: str = "", value: float = 0.0, is_value: bool =  
                                              True, prop: UUID | Entity | None = None, optional: str  
                                              | None = None) → dict
```

Dropdown of data or input box.

### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **association** – Data association type from ‘Vertex’ or ‘Cell’.
- **data\_type** – Type of data selectable from ‘Float’, ‘Integer’ or ‘Reference’.
- **data\_group\_type** – [Optional] Select from property\_groups of type. ‘3D vector’, ‘Dip direction & dip’, ‘Strike & dip’, or ‘Multi-element’.
- **parent** – Parameter name corresponding to the parent object.
- **is\_value** – Display the input box or dropdown menu.
- **prop** – Data entity selected in the dropdown menu if ‘is\_value=False’.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.file_parameter(main: bool = True, label: str = 'File choices', file_description:  
                                         tuple = (), file_type: tuple = (), value: str = "", optional: str |  
                                         None = None) → dict
```

File loader for specific extensions.

### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **file\_description** – Title used to describe each type.
- **file\_type** – Extension of files to display.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.float_parameter(main: bool = True, label: str = 'Float data', value: float =  
                                         1.0, vmin: float = 0.0, vmax: float = 100.0, precision: int = 2,  
                                         line_edit: bool = True, optional: str | None = None) → dict
```

Input box for float value.

### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **vmin** – Minimum value allowed.
- **vmax** – Maximum value allowed.
- **line\_edit** – Allow line edit or spin box
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.integer_parameter(main: bool = True, label: str = 'Integer data', value: int = 1, vmin: int = 0, vmax: int = 100, optional: str | None = None) → dict
```

Input box for integer value.

### Parameters

- **main** – Show ui in main.
- **label** – Label identifier.
- **value** – Input value.
- **vmin** – Minimum value allowed.
- **vmax** – Maximum value allowed.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.object_parameter(main: bool = True, label: str = 'Object', mesh_type: tuple =  
(UUID('4b99204c-d133-4579-a916-a9c8b98cfccb'),  
UUID('19730589-fd28-4649-9de0-ad47249d9aba'),  
UUID('58c4849f-41e2-4e09-b69b-01cf4286cded'),  
UUID('b020a277-90e2-4cd7-84d6-612ee3f25051'),  
UUID('9b08bb5a-300c-48fe-9007-d206f971ea92'),  
UUID('6a057fdc-b355-11e3-95be-fd84a7ffcb88'),  
UUID('c94968ea-cf7d-11eb-b8bc-0242ac130003'),  
UUID('7caebe0e-d16e-11e3-bc69-e4632694aa37'),  
UUID('77ac043c-fe8d-4d14-8167-75e300fb835a'),  
UUID('48f5054a-1c5c-4ca4-9048-80f36dc60a06'),  
UUID('6832acf3-78aa-44d3-8506-9574a3510c44'),  
UUID('e79f449d-74e3-4598-9c9c-351a28b8b69e'),  
UUID('b99bd6e5-4fe1-45a5-bd2f-75fc31f91b38'),  
UUID('88087fb8-76ae-445b-9cdf-68dbce530404'),  
UUID('849d2f3e-a46e-11e3-b401-2776bd4f982'),  
UUID('4ea87376-3ece-438b-bf12-3479733ded46'),  
UUID('202c5db1-a56d-4004-9cad-baaf8899406'),  
UUID('275ecee9-9c24-4378-bf94-65f3c5fbe163'),  
UUID('f26feba3-aded-494b-b9e9-b2bbcbe298e1'),  
UUID('f495cd13-f09b-4a97-9212-2ea392aeb375'),  
UUID('0b639533-f35b-44d8-92a8-f70ecff3fd26')), value: str  
= None, optional: str | None = None) → dict
```

Dropdown menu of objects of specific types.

#### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input value.
- **mesh\_type** – Type of selectable objects.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

#### Returns

Ui\_json compliant dictionary.

```
geoh5py.ui_json.templates.optional_parameter(state: str) → dict[str, bool]
```

Returns dictionary to make existing ui optional via .update() method.

#### Parameters

**state** – Initial state of optional parameter. Can be ‘enabled’ or ‘disabled’.

```
geoh5py.ui_json.templates.string_parameter(main: bool = True, label: str = 'String data', value: str =  
'data', optional: str | None = None) → dict
```

Input box for string value.

#### Parameters

- **main** – Show form in main.
- **label** – Label identifier.
- **value** – Input string value.
- **optional** – Make optional if not None. Initial state provided by not None value. Can be either ‘enabled’ or ‘disabled’.

**Returns**

Ui\_json compliant dictionary.

**geoh5py.ui\_json.utils**

`geoh5py.ui_json.utils.collect(ui_json: dict[str, dict], member: str, value: Any = None) → dict[str, Any]`

Collects ui parameters with common field and optional value.

`geoh5py.ui_json.utils.container_group2name(value)`

`geoh5py.ui_json.utils.dependency_requires_value(ui_json: dict[str, dict], parameter: str) → bool`

Handles dependency and optional requirements.

If dependency doesn't require a value then the function returns False. But if the dependency does require a value, the return value is either True, or will take on the enabled state if the dependent parameter is optional.

**Parameters**

- **ui\_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.find_all(ui_json: dict[str, dict], member: str, value: Any = None) → list[str]`

Returns names of all collected parameters.

`geoh5py.ui_json.utils.flatten(ui_json: dict[str, dict]) → dict[str, Any]`

Flattens ui.json format to simple key/value pair.

`geoh5py.ui_json.utils.group_enabled(group: dict[str, dict]) → bool`

Return true if groupOptional and enabled are both true.

**Parameters**

**group** – UI.json dictionary

`geoh5py.ui_json.utils.group_optional(ui_json: dict[str, dict], group_name: str) → bool`

Returns groupOptional bool for group name.

`geoh5py.ui_json.utils.group_requires_value(ui_json: dict[str, dict], parameter: str) → bool`

True is groupOptional and group is enabled else False

**Parameters**

- **ui\_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.inf2str(value)`

`geoh5py.ui_json.utils.is_form(var) → bool`

Return true if dictionary ‘var’ contains both ‘label’ and ‘value’ members.

`geoh5py.ui_json.utils.is_uijson(ui_json: dict[str, dict])`

Returns True if dictionary contains all the required parameters.

`geoh5py.ui_json.utils.list2str(value)`

`geoh5py.ui_json.utils.monitored_directory_copy(directory: str, entity: ObjectBase, copy_children: bool = True)`

Create a temporary geoh5 file in the monitoring folder and export entity for update.

**Parameters**

- **directory** – Monitoring directory
- **entity** – Entity to be updated
- **copy\_children** – Option to copy children entities.

`geoh5py.ui_json.utils.none2str(value)`

`geoh5py.ui_json.utils.optional_requires_value(ui_json: dict[str, dict], parameter: str) → bool`

True if enabled else False.

#### Parameters

- **ui\_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.path2workspace(value)`

`geoh5py.ui_json.utils.requires_value(ui_json: dict[str, dict], parameter: str) → bool`

Check if a ui.json parameter requires a value (is not optional).

The required status of a parameter depends on a hierarchy of ui switches. At the top is the groupOptional switch, below that is the dependency switch, and on the bottom is the optional switch. When group optional is disabled all parameters in the group are not required, When the groupOptional is enabled the required status of a parameter depends first any dependencies and lastly on it's optional status.

#### Parameters

- **ui\_json** – UI.json dictionary
- **parameter** – Name of parameter to check type.

`geoh5py.ui_json.utils.set_enabled(ui_json: dict, parameter: str, value: bool)`

Set enabled status for an optional or groupOptional parameter.

#### Parameters

- **ui\_json** – UI.json dictionary
- **parameter** – Parameter name.
- **value** – Boolean value set to parameter's enabled member.

`geoh5py.ui_json.utils.str2inf(value)`

`geoh5py.ui_json.utils.str2list(value)`

`geoh5py.ui_json.utils.str2none(value)`

`geoh5py.ui_json.utils.truth(ui_json: dict[str, dict], name: str, member: str) → bool`

Return parameter's 'member' value with default value for non-existent members.

`geoh5py.ui_json.utils.workspace2path(value)`

## geoh5py.ui\_json.validation

```
class geoh5py.ui_json.validation.InputValidation(validators: dict[str, BaseValidator] = None,
                                                 validations: dict[str, Any] | None = None,
                                                 workspace: Workspace = None, ui_json: dict[str, Any] | None = None, validation_options: dict[str, Any] | None = None)
```

Bases: object

Validations on dictionary of parameters.

### Attributes

#### validations

[Validations dictionary with matching set of input parameter keys.]

#### workspace (optional)

[Workspace instance needed to validate uuid types.]

**ignore\_requirements (optional): Omit raising error on ‘required’ validator.**

### Methods

<b>validate_data(data)</b>	Validates data of params and contents/type/shape/keys/reqs of values.
----------------------------	---

```
static infer_validations(ui_json: dict[str, Any] | None, validations: dict[str, dict] | None = None) → dict
```

Infer necessary validations from ui json structure.

```
validate(name: str, value: Any, validations: dict[str, Any] = None)
```

Run validations on a given key and value.

#### Parameters

- **name** – Parameter identifier.
- **value** – Input parameter value.
- **validations** – [Optional] Validations provided on runtime

```
validate_data(data: dict[str, Any]) → None
```

Calls validate method on individual key/value pairs in input.

#### Parameters

**data** – Input data with known validations.

```
property validations
```

```
property validators
```

```
property workspace
```

## 2.3.7 geoh5py.workspace

### geoh5py.workspace.workspace

```
class geoh5py.workspace.workspace.Workspace(h5file: str | Path | io.BytesIO = 'Analyst.geoh5', mode='a',  
                                            **kwargs)
```

Bases: AbstractContextManager

The Workspace class manages all Entities created or imported from the *geoh5* structure.

The basic requirements needed to create a Workspace are:

#### Parameters

**geoh5** – File name of the target *geoh5* file. A new project is created if the target file cannot be found on disk.

#### activate()

Makes this workspace the active one.

In case the workspace gets deleted, Workspace.active() safely returns None.

#### static active() → *Workspace*

Get the active workspace.

#### property attribute\_map: dict

Mapping between names used in the geoh5 database.

#### close()

Close the file and clear properties for future open.

#### property contributors: ndarray

numpy.array of str List of contributors name.

```
classmethod copy_property_groups(entity: ObjectBase, property_groups: list[PropertyGroup],  
                                 data_map: dict)
```

#### copy\_to\_parent(entity, parent, copy\_children: bool = True, omit\_list: tuple = ())

Copy an entity to a different parent with copies of children.

#### Parameters

- **entity** – Entity to be copied.
- **parent** – Target parent to copy the entity under.
- **copy\_children** – Copy all children of the entity.
- **omit\_list** – List of property names to omit on copy

#### Returns

The Entity registered to the workspace.

```
create_data(entity_class, entity_kwargs: dict, entity_type_kwargs: dict | DataType) → Data | None
```

Create a new Data entity with attributes.

#### Parameters

- **entity\_class** – *Data* class.
- **entity\_kwargs** – Properties of the entity.
- **entity\_type\_kwargs** – Properties of the entity\_type.

**Returns**

The newly created entity.

**create\_entity**(entity\_class, save\_on\_creation: bool = True, \*\*kwargs) → [Entity](#) | None

Function to create and register a new entity and its entity\_type.

**Parameters**

- **entity\_class** – Type of entity to be created
- **save\_on\_creation** – Save the entity to geoh5 immediately

**Return entity**

Newly created entity registered to the workspace

**create\_from\_concatenation**(attributes)

**create\_object\_or\_group**(entity\_class, entity\_kwargs: dict, entity\_type\_kwargs: dict) → [Group](#) | [ObjectBase](#) | None

Create an object or a group with attributes.

**Parameters**

- **entity\_class** – [ObjectBase](#) or [Group](#) class.
- **entity\_kwargs** – Attributes of the entity.
- **entity\_type\_kwargs** – Attributes of the entity\_type.

**Returns**

A new Object or Group.

**property data: list[[data.Data](#)]**

Get all active Data entities registered in the workspace.

**deactivate()**

Deactivate this workspace if it was the active one, else does nothing.

**property distance\_unit: str**

str Distance unit used in the project.

**fetch\_array\_attribute**(entity: [Entity](#), key: str = 'cells') → ndarray

Fetch attribute stored as structured array from the source geoh5.

**Parameters**

- **entity** – Unique identifier of target entity.
- **file** – h5py.File or name of the target geoh5 file
- **key** – Field array name

**Returns**

Structured array.

**fetch\_children**(entity: [Entity](#) | None, recursively: bool = False) → list

Recover and register children entities from the geoh5.

**Parameters**

- **entity** – Parental entity.
- **recursively** – Recover all children down the project tree.
- **file** – h5py.File or name of the target geoh5 file.

**Return list**

List of children entities.

**fetch\_concatenated\_attributes**(entity: Group | ObjectBase) → dict | None

Fetch attributes of ConcatenatedData entities.

**Parameters**

**entity** – Concatenator group.

**Returns**

Dictionary of attributes.

**fetch\_concatenated\_list**(entity: Group | ObjectBase, label: str) → list | None

Fetch list of data or indices of ConcatenatedData entities.

**Parameters**

- **entity** – Concatenator group.
- **label** – Label name of the h5py.Group

**Returns**

List of concatenated Data names.

**fetch\_concatenated\_values**(entity: Group | ObjectBase, label: str) → tuple | None

Fetch data under the ConcatenatedData Data group of an entity.

**Parameters**

- **entity** – Concatenator group.
- **label** – Name of the target data.

**Returns**

Index array and data values for the target label.

**fetch\_file\_object**(uid: uuid.UUID, file\_name: str) → bytes | None

Fetch an image from file name.

**Parameters**

**uid** – Unique identifier of target data object.

**Returns**

Array of values.

**fetch\_metadata**(uid: uuid.UUID, argument='Metadata') → dict | None

Fetch the metadata of an entity from the source geoh5.

**Parameters**

- **uid** – Entity uid containing the metadata.
- **argument** – Optional argument for other json-like attributes.

**Returns**

Dictionary of values.

**fetch\_or\_create\_root()**

**fetch\_property\_groups**(entity: Entity) → list[PropertyGroup]

Fetch all property\_groups on an object from the source geoh5

**Parameters**

**entity** – Target object

**Returns**

List of PropertyGroups

**fetch\_type**(*uid: UUID, entity\_type: str*) → dict

Fetch attributes of a specific entity type. :param uid: Unique identifier of the entity type. :param entity\_type: One of ‘Data’, ‘Object’ or ‘Group’

**fetch\_values**(*entity: Entity*) → np.ndarray | str | float | None

Fetch the data values from the source geoh5.

**Parameters**

**entity** – Entity with ‘values’.

**Returns**

Array of values.

**finalize()** → None

Deprecate method finalize

**Parameters**

**file** – h5py.File or name of the target geoh5 file

**find\_data**(*data\_uid: uuid.UUID*) → Entity | None

Find an existing and active Data entity.

**find\_entity**(*entity\_uid: uuid.UUID*) → Entity | None

Get all active entities registered in the workspace.

**find\_group**(*group\_uid: uuid.UUID*) → group.Group | None

Find an existing and active Group object.

**find\_object**(*object\_uid: uuid.UUID*) → object\_base.ObjectBase | None

Find an existing and active Object.

**find\_type**(*type\_uid: uuid.UUID, type\_class: type[EntityType]*) → EntityType | None

Find an existing and active EntityType

**Parameters**

**type\_uid** – Unique identifier of target type

**property ga\_version: str**

str Version of Geoscience Analyst software.

**property geoh5: File**

Instance of h5py.File.

**get\_entity**(*name: str | uuid.UUID*) → list[Entity] | None]

Retrieve an entity from one of its identifier, either by name or uuid.UUID.

**Parameters**

**name** – Object identifier, either name or uid.

**Returns**

List of entities with the same given name.

**property groups: list[groups.Group]**

Get all active Group entities registered in the workspace.

```
property h5file: str | Path | io.BytesIO

Str
    Target geoh5 file name with path.

property list_data_name: dict[uuid.UUID, str]
    dict of uuid.UUID keys and name values for all registered Data.

property list_entities_name: dict[uuid.UUID, str]

Returns
    dict of uuid.UUID keys and name values for all registered Entities.

property list_groups_name: dict[uuid.UUID, str]
    dict of uuid.UUID keys and name values for all registered Groups.

property list_objects_name: dict[uuid.UUID, str]
    dict of uuid.UUID keys and name values for all registered Objects.

load_entity(uid: uuid.UUID, entity_type: str, parent: Entity = None) → Entity | None
    Recover an entity from geoh5.

Parameters
    • uid – Unique identifier of entity
    • entity_type – One of entity type ‘group’, ‘object’, ‘data’ or ‘root’

Return entity
    Entity loaded from geoh5

property name: str
    str Name of the project.

property objects: list[objects.ObjectBase]
    Get all active Object entities registered in the workspace.

open(mode: str | None = None) → Workspace
    Open a geoh5 file and load the tree structure.

Parameters
    mode – Optional mode of h5py.File. Defaults to ‘r+’.

Returns
    self

remove_children(parent, children: list)
    Remove a list of entities from a parent. The target entities remain present on file.

remove_entity(entity: Entity)
    Function to remove an entity and its children from the workspace.

remove_none_referents(referents: dict[uuid.UUID, ReferenceType], rtype: str)
    Search and remove deleted entities

remove_recursively(entity: Entity)
    Delete an entity and its children from the workspace and geoh5 recursively

property repack: bool
    Flag to repack the file after data deletion
```

**property root: Entity | None**

*RootGroup* entity.

**save\_entity(entity: Entity, add\_children: bool = True) → None**

Save or update an entity to geoh5.

#### Parameters

- **entity** – Entity to be written to geoh5.
- **add\_children** – Add children entities to geoh5.
- **file** – h5py.File or name of the target geoh5

**save\_entity\_type(entity\_type: EntityType) → None**

Save or update an entity\_type to geoh5.

#### Parameters

**entity\_type** – Entity to be written to geoh5.

**static str\_from\_type(entity) → str | None**

**property types: list[EntityType]**

Get all active entity types registered in the workspace.

**update\_attribute(entity: Entity | EntityType, attribute: str, channel: str = None, \*\*kwargs) → None**

Save or update an entity to geoh5.

#### Parameters

- **entity** – Entity to be written to geoh5.
- **attribute** – Name of the attribute to get updated to geoh5.
- **channel** – Optional channel argument for concatenated data and index.

**property version: float**

float Version of the geoh5 file format.

**property workspace: Workspace**

This workspace instance itself.

geoh5py.workspace.workspace.**active\_workspace(workspace: Workspace)**

## 2.4 GEOH5 Format

### 2.4.1 About

The  
GEOH5  
for-  
mat  
aims  
to  
pro-  
vide  
a

robust means of handling large quantities of diverse data required in geo-science. The file structure builds on the generic qualities of the

Geoscience **ANALYST** data model, and attempts to maintain a certain level of simplicity and consistency throughout. It is based entirely on free and open **HDF5 technology**. Given that this specification is public, the file format could, with further investment and involvement, become a useful exchange format for the broader geoscientific community.

## Why GEOH5?

- **Leverages properties**  
Fast I/O, compression, cross-platform
- **Content readable and writable**  
We recommend using

HD-  
FView,  
along  
with  
Geo-  
science  
AN-  
A-  
LYST,  
when  
learn-  
ing  
the  
for-  
mat.

- **Easily extensible to**

It  
is  
in-  
tended  
for  
Geo-  
science  
AN-  
A-  
LYST  
to  
pre-  
serve  
data  
it  
does  
not  
un-  
der-  
stand  
(and  
gen-  
er-  
ally  
be

er-  
ant  
with  
re-  
gards  
to  
miss-  
ing  
in-  
for-

mation) when

loading and saving geoh5 files. This will allow third parties to write to this format fairly easily, as well as include additional information not included in this spec for their own purposes. In the current implementation, Geoscience ANALYST automatically removes unnecessary information on save.

## 2.4.2 Definition

The following sections define the structure and components making up the GEOH5 file format.

### Workspace

The bulk of the data is accessible both directly by UUID through the

flat  
HDF5  
groups  
or  
through  
a  
hi-  
er-  
ar-  
chy  
of  
**hard**

chy.

## Types

- *Data Types:* Flat container for all data types
- *Group Types:* Flat container for all group types
- *Object Types:* Flat container for all object types

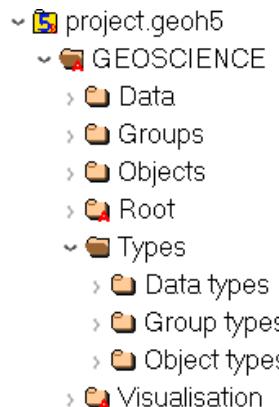

Fig. 2.1: As seen in HD-FView

While all groups, objects and data entities are written into their respective base folder, they also hold links to their children entities to allow for traversals. There is no data duplication, merely multiple references (pointers) to the data storage on file. Types are shared (and thus generally written to file first). All groups, objects and data must include a hard link to their type.

## Attributes

### Version

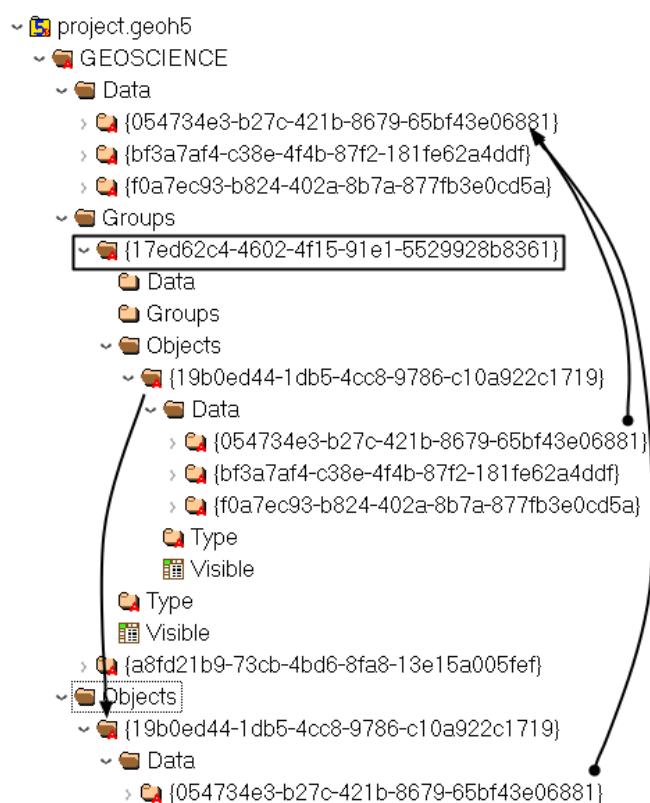

`double Version` of specification used by this file

### Distance unit

`str feet` or (default) `metres` Distance unit of all data enclosed

### Contributors

1D array of `str` (Optional) List of users who contributed to this workspace

## Groups

Groups are simple container for other groups and objects. They are often used to assign special meanings to a collection of entities or to create specialized software functionality.

### Attributes

#### Name

str Name of the object displayed in the project tree.

#### ID

str, *UUID* Unique identifier of the group.

#### Visible

int, 0 or (default) 1 Set visible in the 3D camera (checked in the object tree).

#### Public

int, 0 or (default) 1 Set accessible in the object tree and other parts of the user interface.

#### Clipping IDs

1D array of *UUID* (Optional) List of unique identifiers of clipping plane objects.

#### Allow delete

int, 0 or (default) 1 (Optional) User interface allows deletion.

#### Allow move

int, 0 or (default) 1 (Optional) User interface allows moving to another parent group.

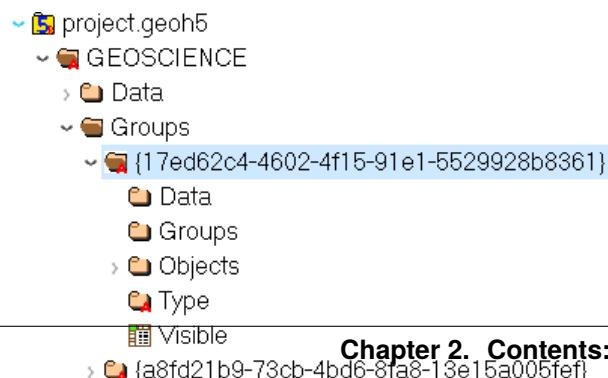

#### Allow rename

int, 0 or (default) 1 (Optional) User interface allows renaming.

#### Metadata

(int, optional) (Optional) Any additional text attached to the group.

The following section describes the supported group types.

## Group Types

*To be further documented*

### Container

#### UUID : {61FBB4E8-A480-11E3-8D5A-2776BDF4F982}

Simple container with no special meaning. Default in Geoscience ANALYST.

### Drillholes

#### UUID : {825424FB-C2C6-4FEA-9F2B-6CD00023D393}

Container restricted to containing drillhole objects, and which may provide convenience functionality for the drillholes within.

### No Type (Root)

#### UUID : {dd99b610-be92-48c0-873c-5b5946ea2840}

The Root group defines the tree structure used in Geoscience ANALYST describing the parent-child relationships of entities. If absent, any Groups/Objects/Data will be brought into Geoscience ANALYST under the workspace group, still respecting any defined hierarchy links.

### SimPEG

#### UUID : {55ed3daf-c192-4d4b-a439-60fa987fe2b8}

Container group for SimPEG inversions. Contains

### Datasets

#### Metadata

json formatted string

Dictionary of inversion options.

#### options

ui.json formatted string

Dictionary holding the corresponding ui.json.

## Tools

### UUID : {a2befc38-3207-46aa-95a2-16b40117a5d8}

Group for slicer and label objects.

*Not yet geoh5py implemented*

*To be further documented*

## Maxwell

### UUID : {1c4122b2-8e7a-4ec3-8d6e-c818495adac7}

Group for Maxwell plate modeling application.

*Not yet geoh5py implemented*

*To be further documented*

## GIFTools

GIFtools group containers

### GIFTools Project

#### UUID : {585b3218-c24b-41fe-ad1f-24d5e6e8348a}

*Not yet geoh5py implemented*

*To be documented*

### GIF Executables

#### UUID : {afae95ef-c2a7-4aec-9800-0d19bd2c2c07}

*Not yet geoh5py implemented*

*Not yet geoh5py implemented*

*To be documented*

## Geophysics

**UUID : {151778d9-6cc0-4e72-ba08-2a80a4fb967f}**

*Not yet geoh5py implemented*

*To be documented*

## Geotechnical

**UUID : {391a616b-3833-11e4-a7fb-fcddabfddab1}**

*Not yet geoh5py implemented*

*To be documented*

## Equipment

**UUID : {8beac9ff-3829-11e4-8654-fcddabfddab1}**

*Not yet geoh5py implemented*

*To be documented*

---

**Note:** Though this file format technically allows objects/groups to appear within multiple groups simultaneously (overlapping lists), this is not currently supported by Geoscience ANALYST.

---

## Objects

Objects are containers for Data with spatial information. Most (not all) object geometry is described in terms of vertices (3D locations) and cells (groupings of vertices such as triangles or segments). The exact requirements and interpretation depends on the type.

### Attributes

#### Name

`str` Name of the object displayed in the project tree.

#### ID

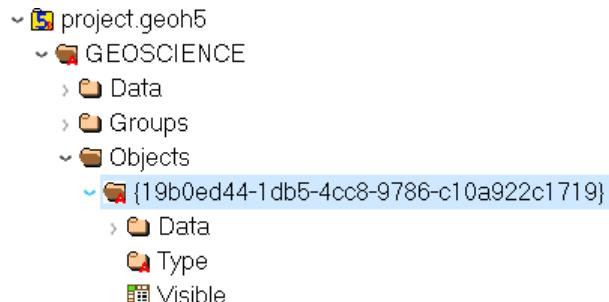

`str` Unique identifier (*UUID*) of the group.

#### Visible

`int`, 0 or (default) 1 Set visible in the 3D camera (checked in the object tree).

#### Public

`int`, 0 or (default) 1 Set accessible in the object tree and other parts of the user interface.

**Clipping IDs**

1D array of UUID (Optional) List of unique identifiers of clipping plane objects.

**Allow delete**

int, 0 or (default) 1 (Optional) User interface allows deletion.

**Allow move**

int, 0 or (default) 1 (Optional) User interface allows moving to another parent group.

**Allow rename**

int, 0 or (default) 1 (Optional) User interface allows renaming.

**Metadata**

(int, optional) (Optional) Any additional text attached to the group.

The following section describes the supported object types and their specific attributes.

## ANALYST Objects

Entities with spatial information used to store data.

### Points

#### UUID : {202C5DB1-A56D-4004-9CAD-BAAFD8899406}

3-D scatter points object defined by vertices with fixed coordinates in Cartesian system (x, y and z).

### Datasets

#### Vertices

1D composite array

[*x* double, *y* double, *z* double]

### Curve

#### UUID : {6A057FDC-B355-11E3-95BE-FD84A7FFCB88}

Polyline object defined by a series of line segments (cells) connecting vertices. Data can be associated to either the vertices or cells.

## Attributes

### Current line property ID

str, *UUID*

Unique identifier of a reference data for naming of curve parts.

## Datasets

### Cells

Array of int32, shape(N, 2)

Array defining the connection (line segment) between pairs of vertices.

## Surface

UUID : {F26FEBA3-ADED-494B-B9E9-B2BBCBE298E1}

Triangulated mesh object defined by cells (triangles) and vertices.

## Datasets

### Cells

Array of int32, shape(N, 3)

Array defining the connection between triplets of vertices, representing triangles.

## Block model

UUID : {B020A277-90E2-4CD7-84D6-612EE3F25051}

Rectilinear grid of cells defined along three orthogonal axes (U,V and Z) of length nU, nV and nZ respectively. The conversion between the array coordinates of a cell to a 1-D vector index can be calculated from

```
cell index = k + i*nZ + j*nU*nZ
```

Without rotation angles, U points eastwards, V points northwards, and Z points upwards. Since their geometry is defined entirely by the additional data described below, block models do not require a Vertices or Cells dataset.

## Datasets

### U cell delimiters

array of double, shape(nU,)

Distances of cell edges from origin along the U axis (first value should be 0)

### V cell delimiters

array of double, shape(nV,)

Distances of cell edges from origin along the V axis (first value should be 0)

**Z cell delimiters**

array of double, shape(nZ,)

Distances of cell edges from origin upwards along the vertical axis (first value should be 0)

**Attributes****Origin**

composite type

[X double, Y double, Z double]

Origin point of grid

**Rotation**

double (default) 0 Counterclockwise angle (degrees) of rotation around the vertical axis in degrees.

**2D Grid**

**UUID : {48f5054a-1c5c-4ca4-9048-80f36dc60a06}**

Rectilinear grid of cells defined along two orthogonal axes (U and V) of length nU and nV. The conversion between the grid coordinates of a cell to its 1-D vector index can be calculated from

```
cell index = i + j*nU
```

Without rotation angles, U points eastwards and V points northwards. Since their geometry is defined entirely by the additional data described below, 2D grids do not require a Vertices or Cells dataset.

**Attributes****Origin**

composite type

[X double, Y double, Z double]

Origin point of the grid.

**U Size**

double Length of U axis

**U Count**

double Number of cells along U axis

**V Size**

double Length of V axis

**V Count**

double Number of cells along V axis

**Rotation**

double (Optional) Counterclockwise angle (degrees) of rotation around the vertical axis at the Origin.

**Vertical**

char, 0(false, default) or 1(true)) (Optional) If true, V axis is vertical (and rotation defined around the V axis)

## Drillhole

**UUID : {7CAEBF0E-D16E-11E3-BC69-E4632694AA37}**

Object representing boreholes defined by a collar location and survey parameters. Vertices represent points along the drillhole path (support for data rather than the drillhole geometry itself) and must have a Depth property value. Cells contain two vertices and represent intervals along the drillhole path (and are a support for interval data as well). Cells may overlap with each other to accommodate the different sampling intervals of various data.

## Attributes

### Collar

composite type, shape(3,)

[*X* double, *Y* double, *Z* double]

Collar location

## Datasets

### Surveys

composite array, shape(3,)

[*Depth* double, *Dip* double, *Azimuth* double]

Survey locations

### Trace

1D composite array

[*X* double, *Y* double, *Z* double]

Points forming the drillhole path from collar to end of hole. Must contain at least two points.

## Geoimage

**UUID : {77AC043C-FE8D-4D14-8167-75E300FB835A}**

*Not yet geoh5py implemented*

*To be further documented*

Vertices represent the four corners of the geolocated image. No cell data. An object-associated file-type data containing the image to display is expected to exist under this object.

---

**Note:** Should be arranged as a rectangle currently, since Geoscience ANALYST does not currently support skewed images.

---

## Label

**UUID : {E79F449D-74E3-4598-9C9C-351A28B8B69E}**

*Not yet geoh5py implemented*

*To be further documented*

Has no vertices nor cell data

## Attributes

### Target position

composite type, shape(3,)

[X double, Y double, Z double]

The target location of the label

### Label position

composite type, shape(3,)

[X double, Y double, Z double] (Optional - Defaults to same as target position ) The location where the text of the label is displayed

## Slicer

**UUID : {238f961d-ae63-43de-ab64-e1a079271cf5}**

*Not yet geoh5py implemented*

*To be further documented*

## Target

**UUID : {46991a5c-0d3f-4c71-8661-354558349282}**

*Not yet geoh5py implemented*

*To be further documented*

## ioGAS Points

**UUID : {d133341e-a274-40e7-a8c1-8d32fb7f7eaf}**

*Not yet geoh5py implemented*

*To be further documented*

## Maxwell Plate

**UUID : {878684e5-01bc-47f1-8c67-943b57d2e694}**

*Not yet geoh5py implemented*

*To be further documented*

## Octree

**UUID : {4ea87376-3ece-438b-bf12-3479733ded46}**

Semi-structured grid that stores cells in a tree structure with eight octants.

## Datasets

### Octree Cells

composite type, shape(N, 4)

[*I integer, J integer, K integer, NCells integer*]

Array defining the position (I, J, K) and size (NCells) of every cell within the base octree grid.

## Attributes

### NU

*integer* Number of base cells along the U-axis.

### NV

*integer* Number of base cells along the V-axis.

### NW

*integer* Number of base cells along the W-axis.

### Origin

composite type, shape(3,)

[*X double, Y double, Z double*]

Origin point of the grid.

### Rotation

*double* (default) 0 Counterclockwise angle (degrees) of rotation around the vertical axis in degrees.

### U Cell Size

*double* Base cell dimension along the U-axis.

### V Cell Size

*double* Base cell dimension along the V-axis.

### W Cell Size

*double* Base cell dimension along the W-axis.

## Text Object

**UUID : {c00905d1-bc3b-4d12-9f93-07fcf1450270}**

*Not yet geoh5py implemented*

*To be further documented*

## Potential Electrode

**UUID : {275ecee9-9c24-4378-bf94-65f3c5fbe163}**

*Curve* object representing the receiver electrodes of a direct-current resistivity survey.

## Datasets

### Metadata

json formatted string

Dictionary defining the link between the source and receiver objects.

- “Current Electrodes” uuid: Identifier for the linked *Current Electrode*
- “Potential Electrodes” uuid: Identifier for the linked *Potential Electrode*

## Requirements

### A-B Cell ID

Data entity

Reference data named “A-B Cell ID” with association=CELL expected. The values define the source dipole (cell) from the *Current Electrode* to every potential measurement.

## Current Electrode

**UUID : {9b08bb5a-300c-48fe-9007-d206f971ea92}**

*Curve* object representing the transmitter electrodes of a direct-current resistivity survey.

## Datasets

### Metadata

json formatted string

Dictionary defining the link between the source and receiver objects. Same definition as the *Potential Electrode* object.

## Requirements

### A-B Cell ID

Data entity

Reference data named “A-B Cell ID” with association=CELL defining a unique identifier to every unique dipole sources. For “pole” sources, the cell attribute references twice to the same vertex.

## VP Model

**UUID : {7d37f28f-f379-4006-984e-043db439ee95}**

*Not yet geoh5py implemented*

*To be further documented*

## Airborne EM

**UUID : {fdf7d01e-97ab-43f7-8f2c-b99cc10d8411}**

*Not yet geoh5py implemented*

*To be further documented*

## Airborne TEM Rx

**UUID : {19730589-fd28-4649-9de0-ad47249d9aba}**

*Curve* object representing an array of time-domain electromagnetic receiver dipoles.

## Attributes

### Target position

composite type

## Datasets

### Metadata

json formatted string

Dictionary of survey parameters shared with the *Transmitters*. The following items are core parameters stored under the “EM Dataset” key.

- “**Channels**”: **list of double**  
Time channels at which data are recorder.
- “**Input type**”: **string**  
Type of survey from “Rx”, “Tx” or “Tx and Rx”
- “**Loop radius**”: **double**  
Transmitter loop radius.
- “**Property groups**”: **list of uuid**  
Reference to property groups containing data at every channel.

- “**Receivers**”: **uuid**  
Unique identifier referencing to itself.
- “**Survey type**”: **string**  
Defaults to “Airborne TEM”.
- “**Transmitters**”: **uuid**  
Unique identifier referencing to the linked transmitters entity.
- “**Unit**”: **string**  
Sampling units, must be one of “Seconds (s)”, “Milliseconds (ms)”, “Microseconds (us)” or “Nanoseconds (ns)”.
- “**Crossline offset property**” **uuid** OR “**Crossline offset value**” **double**:  
Offline offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- “**Inline offset property**” **uuid** OR “**Crossline offset value**” **double**:  
Inline offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- “**Inline offset property**” **uuid** OR “**Crossline offset value**” **double**:  
Vertical offset between the receivers and transmitters, either defined locally on vertices as a property OR globally as a constant value.
- “**Yaw property**” **uuid** OR “**Yaw value**” **double**:  
Rotation (angle) of the transmitter loop as measured on the UV-plane (+ clockwise), either defined locally on vertices as a property OR globally as a constant value.
- “**Pitch property**” **uuid** OR “**Pitch value**” **double**:  
Tilt angle of the transmitter loop as measured on the VW-plane (+ nose up), either defined locally on vertices as a property OR globally as a constant value.
- “**Roll property**” **uuid** OR “**Roll value**” **double**:  
Banking angle of the transmitter loop as measured on the UW-plane (+ right-wing down), either defined locally on vertices as a property OR globally as a constant value.
- “**Waveform**” **dict**:
  - “**Discretization**” **array of double, shape(N, 2)**:  
Array of times and normalized currents (Amp) describing the source impulse over a discrete interval (e.g.  $[[t\_1, c\_1], [t\_2, c\_2], \dots, [t\_N, c\_N]]$ )
  - “**Timing mark**” **double**:  
Reference timing mark measured from the beginning of the “Discretization”. Generally used as the reference ( $t\_i=0.0$ ) for the provided data channels: (-) on-time and (+) off-time.

## Airborne TEM Tx

UUID : {58c4849f-41e2-4e09-b69b-01cf4286cded}

*Curve* object representing an array of time-domain electromagnetic transmitter loops.

## Datasets

### Metadata

json formatted string

See definition from the [Airborne TEM Rx](#) object. The “Transmitters” uuid value should point to itself, while the “Receivers” uuid refers the linked [Airborne TEM Rx](#) object.

## Airborne FEM Rx

**UUID : {b3a47539-0301-4b27-922e-1dde9d882c60}**

*Not yet geoh5py implemented*

*To be further documented*

## Airborne FEM Tx

**UUID : {a006cf3e-e24a-4c02-b904-2e57b9b5916d}**

*Not yet geoh5py implemented*

*To be further documented*

## Airborne Gravity

**UUID : {b54f6be6-0eb5-4a4e-887a-ba9d276f9a83}**

*Not yet geoh5py implemented*

*To be further documented*

## Airborne Magnetics

**UUID : {4b99204c-d133-4579-a916-a9c8b98cfccb}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground Gravity

**UUID : {5ffa3816-358d-4cdd-9b7d-e1f7f5543e05}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground Magnetics

**UUID : {028e4905-cc97-4dab-b1bf-d76f58b501b5}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground Gradient IP

**UUID : {68b16515-f424-47cd-bb1a-a277bf7a0a4d}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground EM

**UUID : {09f1212f-2bdd-4dea-8bbd-f66b1030dfcd}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground TEM Rx

**UUID : {41018a45-01a0-4c61-a7cb-9f32d8159df4}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground TEM Tx

**UUID : {98a96d44-6144-4adb-afbe-0d5e757c9dfc}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground TEM Rx (large-loop)

**UUID : {deebe11a-b57b-4a03-99d6-8f27b25eb2a8}**

*Not yet geoh5py implemented*

*To be further documented*

## Ground TEM Tx (large-loop)

UUID : {17dbbfbb-3ee4-461c-9f1d-1755144aac90}

*Not yet geoh5py implemented*

*To be further documented*

## Ground FEM Rx

UUID : {a81c6b0a-f290-4bc8-b72d-60e59964bfe8}

*Not yet geoh5py implemented*

*To be further documented*

## Ground FEM Tx

UUID : {f59d5a1c-5e63-4297-b5bc-43898cb4f5f8}

*Not yet geoh5py implemented*

*To be further documented*

## Magnetotellurics

UUID : {b99bd6e5-4fe1-45a5-bd2f-75fc31f91b38}

*Points* object representing a magnetotelluric survey.

### Metadata

json formatted string

Dictionary of survey parameters. The following items are core parameters stored under the “EM Dataset” key.

- “**Channels**”: **list of double**  
Frequency channels at which data are recorder.
- “**Input type**”: **string**  
Static field set to “Rx only”
- “**Property groups**”: **list of uuid**  
Reference to property groups containing data at every channel.
- “**Receivers**”: **uuid**  
Reference to itself.
- “**Survey type**”: **string**  
Static field set to “Magnetotellurics”
- “**Unit**”: **string**  
Sampling units, must be one of “Hertz (Hz)”, “KiloHertz (kHz)”, “MegaHertz (MHz)” or “Gigahertz (GHz)”.

## Tipper Rx

UUID : {0b639533-f35b-44d8-92a8-f70ecff3fd26}

*Curve* object representing a tipper survey.

### Metadata

json formatted string

Dictionary of survey parameters. The following items are core parameters stored under the “EM Dataset” key.

- “**Channelslist of double**  
Frequency channels at which data are recorder.
- “**Input typestring**  
Static field set to “Rx and base stations”
- “**Property groupslist of uuid**  
Reference to property groups containing data at every channel.
- “**Receiversuuid**  
Reference to itself.
- “**Base stationsuuid**  
Reference to *Tipper Base stations*
- “**Survey typestring**  
Static field set to “Magnetotellurics”
- “**Unitstring**  
Sampling units, must be one of “Hertz (Hz)”, “KiloHertz (kHz)”, “MegaHertz (MHz)” or “Gigahertz (GHz)”.

## Tipper Base stations

UUID : {f495cd13-f09b-4a97-9212-2ea392aeb375}

*Points* object representing a tipper survey.

### Metadata

json formatted string

See definition from the *Tipper Rx* object. The “Base stations” uuid value should point to itself, while the “Receivers” uuid refers the linked *Tipper Rx* object.

## Geoscience INTEGRATOR Objects

List object types specific to INTEGRATOR.

## Points

**UUID : {6832acf3-78aa-44d3-8506-9574a3510c44}**

## Data

Containers for data values of various types. Data are currently **always stored as a 1D array**, even in the case of single-value data with the `Object` association (in which case it is a 1D array of length 1). See the [Data Types](#) section for the list of supported data types.

## Attributes

### Association

`str` Describes which part the property is tied to. Must be one of: `Unknown`, `Object`, `Cell`, `Vertex`, `Face` or `Group`

### Name

`str` Name of the data displayed in the project tree.

### ID

`str` Unique identifier (`UUID`) of the group.

**Visible**

int, 0 or 1 (Optional) Set visible in the 3D camera (checked in the object tree).

**Clipping IDs**

1D array of UUID (Optional) List of unique identifiers of clipping plane objects.

**Allow delete**

int, 0 or (default) 1 (Optional) User interface allows deletion.

**Allow rename**

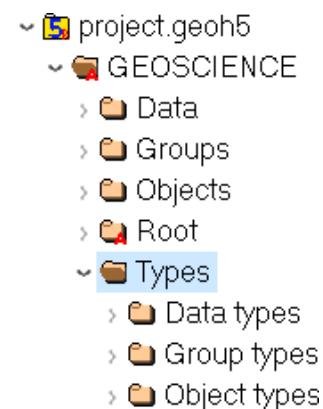

int, 0 or (default) 1 (Optional) User interface allows renaming.

**Public**

int, 0 or (default) 1 (Optional) Set accessible in the object tree and other parts of the user interface.

## Types

While they are structured similarly, **each group, object or set of data has a type that defines how its HDF5 datasets should be interpreted**. This type is shared among any number of entities (groups/objects/data sets).

### Group Types

#### Attributes

**Name**

str Name of the group displayed in the project tree.

**ID**

str Unique identifier (*UUID*) of the group type.

**Description**

str (Optional) Description of the type.

**Allow move contents**

int, 0 or (default) 1 (Optional) User interface allows deletion of the content.

**Allow delete contents**

int, 0 or (default) 1 (Optional) User interface allows deletion of the content.

## Object Types

Objects are containers for data values with spatial information.

### Attributes

#### Name

`str` Name of the object displayed in the project tree.

#### ID

`str` Unique identifier (*UUID*) of the group type.

#### Description

`str` (Optional) Description of the type.

## Data Types

New data types can be created at will by software or users to describe object or group properties. Data of the same type can exist on any number of objects or groups of any type, and each instance can be associated with vertices, cells or the object/group itself. Some data type identifiers can also be reserved as a means of identifying a specific kind of data.

### Attributes

#### Name

`str` Name of the object displayed in the project tree.

#### ID

`str` Unique identifier (*UUID*) of the data type.

Unlike Groups and Objects, Data entities do not generally have fixed identifier Type. Multiple data entities linked by a type will share common properties (color map, units, etc.). Exceptions to this rule are the fixed:

## Geoscience INTEGRATOR Data Set

### Microseismic

`UUID : {9f9fec8-3829-11e4-8654-fcddabfddab1}`

*Not yet geoh5py implemented*

*To be documented*

## Ground Deformation

### Primitive type

`str`

Specifies the kind of data values stored as HDF5 dataset. Must be one of:

## Primitive Types

*To be further documented*

### Float

- Stored as a 1D array of 32-bit float type
- No data value: 1.175494351e-38 (FLT\_MIN, considering use of NaN)

### Integer

- Stored as a 1D array of 32-bit integer type
- No data value: -2147483648 (INT\_MIN, considering use of NaN)

### Text

- Stored as a 1D array of UTF-8 encoded, variable-length string type
- No data value : empty string

### Referenced

- Stored as a 1D array of 32-bit unsigned integer type (native)
- Value map : (1D composite type array dataset - Key (unsigned int), Value (variable-length utf8 string) ) must exist under type
- No data value : 0 (key is tied to value “Unknown”)

### Date/Time

- Stored as a 1D array of variable-length strings formatted according to the [ISO 8601](#) extended specification for representations of UTC dates and times (Qt implementation), taking the form YYYY-MM-DDTHH:mm:ss[Z|[-]HH:mm]
- No data value : empty string

### Filename

- Stored as a 1D array of UTF-8 encoded, variable-length string type designating a file name
- For each file name within “Data”, an opaque dataset named after the filename must be added under the Data instance, containing a complete binary dump of the file
- Different files (under the same object/group) must be saved under different names
- No data value : empty string

**Blob**

- Stored as a 1D array of 8-bit char type (native) (value ‘0’ or ‘1’)
- For each index set to 1, an opaque dataset named after the index (e.g. “1”, “2”, etc) must be added under the Data instance, containing the binary data tied to that index
- No data value : 0

**Description**

**str** (Optional) Description of the type.

**Units**

**str** (Optional) Data units

**Color map**

1D compound array

[*Value double*, *Red uint*, *Green uint*, *Blue uint*, *Alpha uint*]

(Optional) Records colors assigned to value ranges. The *Value* mark the start of the range)

**Value map**

(1D compound array dataset)

[*Key uint*, *Value str*]

Required only for reference data types (classifications)

**Transparent no data**

**int**, 0 or (default) 1 (Optional) Whether or not absence of data/filtered data should be hidden in the viewport.

**Hidden**

**int**, 0 or (default) 1 (Optional) Whether or not the data type should appear in the data type list.

**Scientific notation**

**int**, 0 or (default) 1 (Optional) Whether or not the data values of this type should be displayed in scientific notation.

**Precision**

**int** (Optional) The number of decimals (or significant digits in case of scientific notation) used when displayed data values of this type.

**Number of bins**

**int**, default=50 (Optional) Number of bins used when displaying histogram

**Duplicate type on copy**

**int**, 0 or (default) 1 (Optional) When enabled, a separate copy of this data type will be created and used when data of this type is copied.

## 2.4.3 Standards

General notes on formatting.

- All text data and attributes are variable-length and use UTF-8 encoding
- All numeric data uses INTEL PC native types
- Boolean values are stored using char (0:false, 1:true)
- Anything found in a geoh5 v1.0 file which is not mentioned in this document is optional information

## 2.4.4 External Links

  - [Python](#)
  - [Matlab](#)

## 2.5 UI.JSON Format

### 2.5.1 About

The **ui.json** format provides a schema to create a simple User Interface (UI) between geoh5py and Geoscience ANALYST Pro. The format uses **JSON objects** to represent *script parameters* used in the UI, and pass those parameters to an accompanying python script.

Each ui.json object requires at least a **label** and **value** member, however additional members can be used to define different types of input and additional dependencies between parameters.

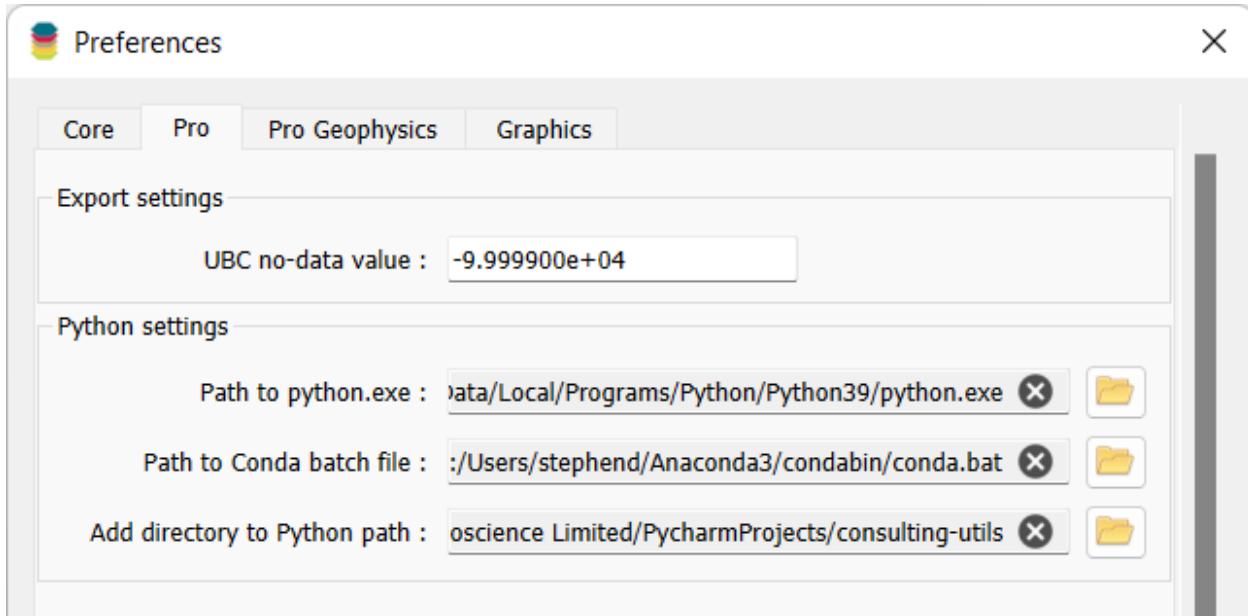

For example, a simple ui.json below describes a single parameter called ‘grid\_object’, which is used to select a block model within a geoh5 file.

```
{  
  "grid_object": {  
    "meshType": ["{B020A277-90E2-4CD7-84D6-612EE3F25051}"],  
    "main": true,  
    "label": "Select Block Model",  
    "value": ""  
  }  
}
```

Note: The **meshType** used to select the grid object is defined by a list of UUID. A complete list of UUID’s for geoh5 object types are available in the [geoh5 objects documentation](#).

## 2.5.2 Usage with Geoscience ANALYST Pro

A ui.json file contains the parameters that reference a Python script to run. Geoscience ANALYST must be configured prior to running the application by setting the path to Python scripts or to a Conda environment as defined by the **conda\_environment** parameter.

### **run\_command str**

Name of python script excluding the .py extension (i.e., “run\_me” for run\_me.py) required for Geoscience ANALYST Pro to run on save or auto-load.

### **conda\_environment str**

Optional name of conda environment to activate when running the python script in *run\_command*

### **title str**

Title of user interface window

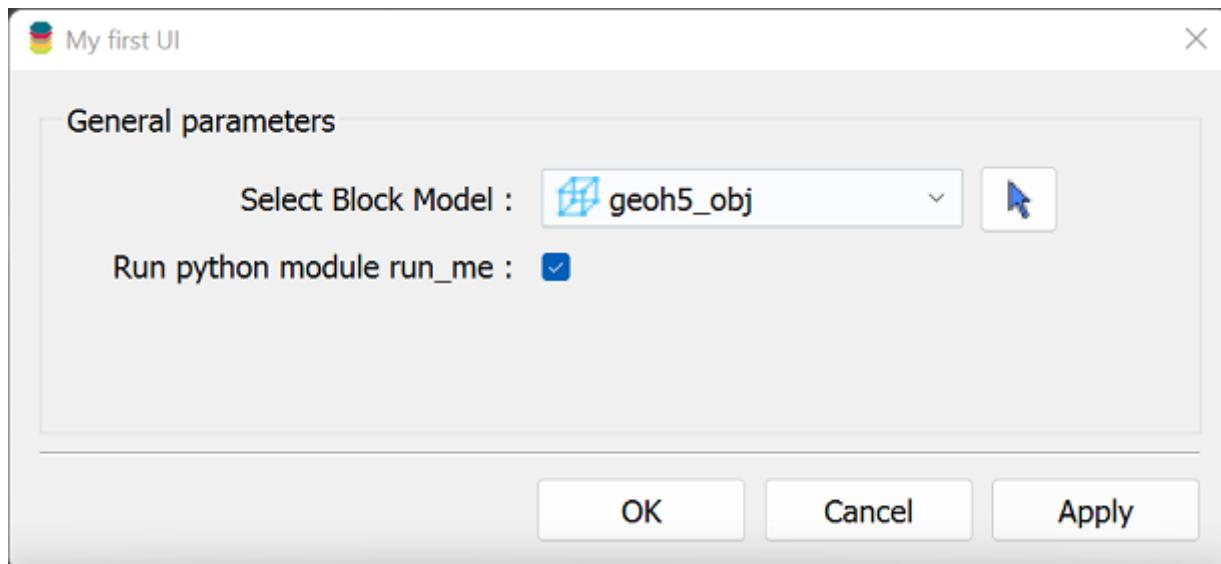

To complete the example above, add the **run\_command**, and **title** parameter to the ui.json file.

```
{
  "grid_object": {
    "meshType": ["{B020A277-90E2-4CD7-84D6-612EE3F25051}"],
    "main": true,
    "label": "Select Block Model",
    "value": ""
  },
  "title": "My first UI",
  "run_command": "run_me"
}
```

Within the accompanying python script, the parameters from the ui.json is passed to the python script as a dictionary of arguments, and can be accessed using the InputFile module of geoh5py as shown below:

```
import sys
from geoh5py.ui_json import InputFile
```

(continues on next page)

(continued from previous page)

```
ui_json = sys.argv[1]
ifile = InputFile.read_ui_json(ui_json)
params = ifile.data

# Get the block model grid object
bm = params["grid_object"]
print(f"The selected object name is {bm.name}")
```

When a **ui.json** is run within Geoscience ANALYST Pro, the following parameters are updated or added:

- The **value** member is updated with the UUID of the object selected in the UI
- The **enabled** member bool is set for whether the parameter is enabled
- The **Data parameter** will also have updated **isValue** and **property** members. The **isValue** bool member is *true* if the **value** member was selected and *false* if the **property** member was selected.

The following JSON objects will be written (and overwritten if given) upon running a ui.json from Geoscience ANALYST Pro:

- **monitoring\_directory** str the absolute path of a monitoring directory. Workspace files written to this folder will be automatically processed by Geoscience ANALYST.
- **workspace\_geoh5** str (Optional) Path to the source geoh5 file (for reference only)
- **geoh5** str the absolute path to the geoh5 written containing all the objects of the workspace within the parameters of the **ui.json**. One only needs to use this workspace along with the JSON file to access the objects with geoh5py.

## 2.5.3 Parameters available for all ui.json objects

The following members are available to all input parameters in the ui.json schema.

### **label str**

Required string describing parameter. A colon will automatically be added within Geoscience ANALYST, so this should be omitted.

### **value str, int, bool , or float**

This required member takes a different form, including the empty string "", depending on the *parameter type*. The value is updated when written from Geoscience ANALYST.

### **main bool**

If set to true, the parameter is shown in the first tab of the UI and will throw an error if not present (and not optional). Optional parameters may be set to main. When main is not given or is false, the parameter will be under the *Optional Parameters* tab.

### **tooltip str**

String describing the parameter in detail that appears when the mouse hovers over it.

### **optional bool**

*true* or *false* on whether the parameter is optional. On output, check if *enabled* is set to true.

### **enabled bool**

*true* or *false* if the parameter is enabled. The default is true. If a parameter is optional and not enabled, it will start as disabled (grey and inactive in the UI).

### **group str**

Name of the group to which the parameter belongs. Adds a box and name around the parameters with the same case-sensitive group name.

### **groupOptional bool**

If true, adds a checkbox in the top of the group box next to the name. The group parameters will be disabled if not checked. The initial state depends on the **groupDependency** and **groupDependencyType** members and the **enabled** member of the group's parameters.

### **dependency str**

The name of the parameter which this parameter is dependent upon. The dependency parameter should be optional or boolean parameter (i.e., has a checkbox).

### **dependencyType str**

What happens when the dependency member is checked. Options are enabled or disabled

### **groupDependency str**

The name of the object of which the group of the parameter is dependent upon. This member will also require the **groupOptional** member to be present and set to *true*. Be sure that the object is not within the group.

### **groupDependencyType str**

What happens when the group's dependency parameter is checked. Options are enabled or disabled.

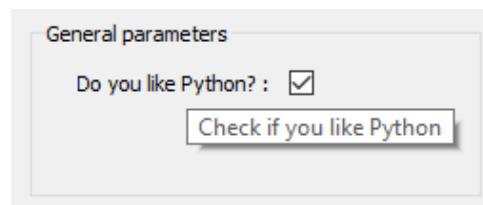

## 2.5.4 Additional Parameters

The following sections define different object specific parameters that can be used in the **ui.json** schema.

### Boolean Parameter

A parameter named “input” that has a bool value.

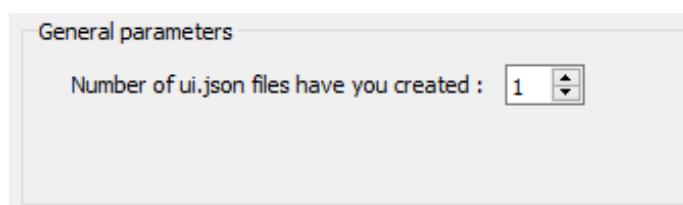

```
{  
  "input": {  
    "main": true,  
    "label": "Do you like Python?",  
    "value": true,  
    "tooltip": "Check if you like Python"  
  }  
}
```

### Integer Parameter

A parameter that has an **int** value. The optional parameters **min** and **max** invoke a validator to insure the bound(s) are enforced.

```
{  
  "file_xp": {  
    "main": true,  
    "label": "Number of ui.json files have you created",  
    "value": 1,  
    "min": 0,  
    "max": 100  
  }  
}
```

## Float Parameter

A parameter that has a `float` value. The optional parameters are:

### `min float`

Minimum value allowed for validator of the `value` member. The default is the minimum numeric limits of float.

### `max float`

Maximum value allowed for validator of the `value` member. The default is the maximum numeric limits of float.

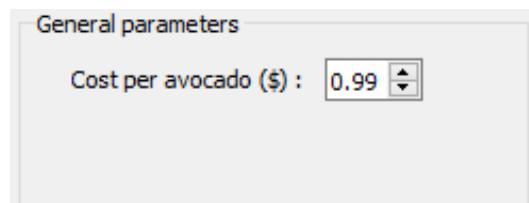

### `lineEdit bool`

Boolean whether to use a line edit (`true`) or a spin box (`false`). The default is true.

### `precision int`

Number of decimal places in the line edit or spin box

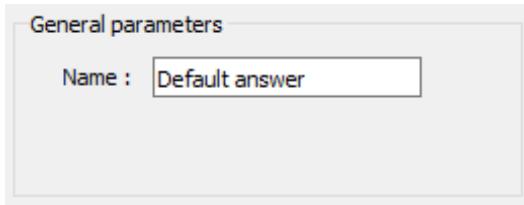

```
{
  "avocado": {
    "main": true,
    "label": "Cost per avocado ($)",
    "value": 0.99,
    "min": 0.29,
    "precision": 2,
    "lineEdit": false,
    "max": 2.79
  }
}
```

## String Parameter

For a simple string parameter, use an empty `str` value to have an empty string. Only a `label` and `value` is required.

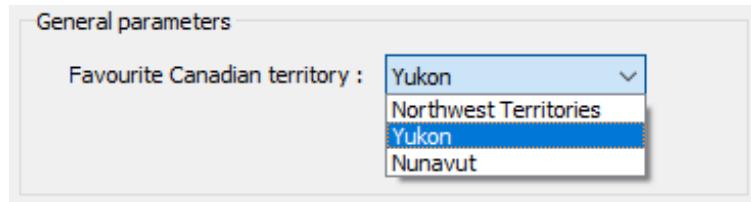

```
{
  "my_string": {
    "main": true,
    "label": "Name",
    "value": "Default answer"
  }
}
```

### Multi-choice string Parameter

For a drop-down selection, add a `choiceList` member with an array of strings (`str`)

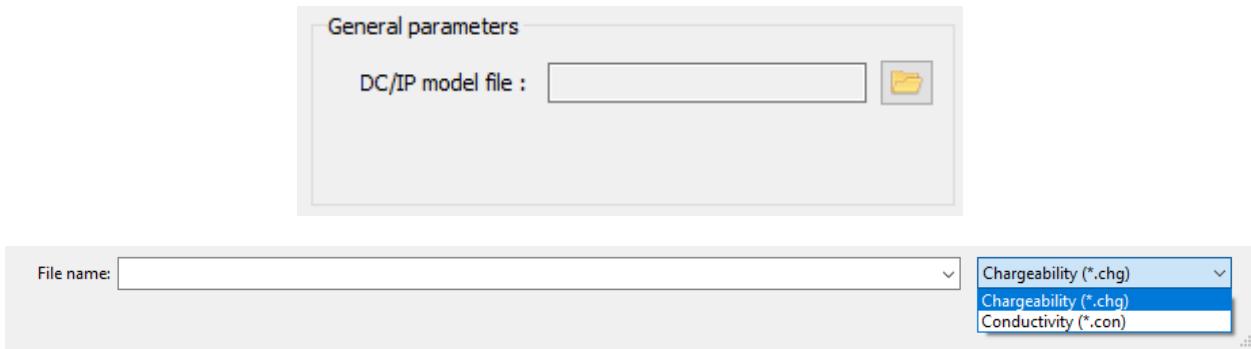

```
{  
    "favourites":  
    {  
        "choiceList": ["Northwest Territories",  
                      "Yukon",  
                      "Nunavut"],  
        "main": true,  
        "label": "Favourite Canadian territory",  
        "value": "Yukon"  
    }  
}
```

### File Parameter

A file parameter comes with an icon to choose the file, with a `str` value. Extra members of the file object parameter are `fileDescription` and `fileType`. Both of these are `str` types and can be arrays, but must be of the same length

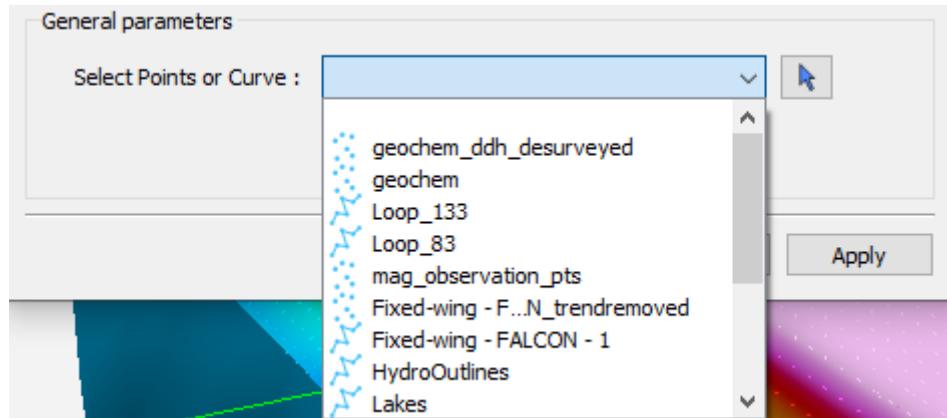

```
{  
    "model_file": {  
        "fileDescription": ["Chargeability", "Conductivity"],  
        "fileType": ["chg", "con"],  
        "main": true,  
        "label": "DC/IP model file",  
        "value": ""  
    }  
}
```

### Geoscience ANALYST Object Parameter

To choose an object from a dropdown menu, the universally unique identifier (UUID) of the *Object Type*: is required for the filtering of objects. This is given as a single or array of str in the member **meshType**. The icon to pick the object comes with this parameter. The value returned is the *UUID* of the Geoscience ANALYST object selected.

```
{
  "interesting_object": {
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,
                 "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],
    "main": true,
    "label": "Select Points or Curve",
    "value": ""
  }
}
```

## Geoscience ANALYST Data parameter

Creating a parameter to choose a Geoscience ANALYST object's data requires extra members:

### **dataType str**

Describes the type of data to filter. One or more (as an array) of these key words: Integer, Float, Text, Referenced, Vector, DataTime, Geometric, Boolean, or Text.

### **association str**

Describes the geometry of the data. One or more of these key words: Vertex, Cell, or Face.

### **parent str**

Either a *UUID* of the parent or the name of the *Object parameter* JSON object to allow the user to choose the mesh.

### **isValue bool**

Describes whether to read the **value** (float) or **property** (str) member. If not given, the value member is an *UUID* and is considered a *drop-down data parameter*. If this member is given along with **property**, then an icon is added to the UI element, which switches between te **value** (line edit) and **property** (drop-down) choices. This value is updated on export depending on the style choice (float or str)

### **property str.**

Data *UUID* that is selected when **isValue** is present. Geoscience ANALYST Pro will update this value on export.

### **min float**

Optional minimum value allowed for validator of the **value** member. The default is the minimum numeric limits of float.

### **max float**

Optional maximum value allowed for validator of the **value** member. The default is the maximum numeric limits of float.

### **precision int**

Optional number of decimal places for the value.

## Drop-down Parameter

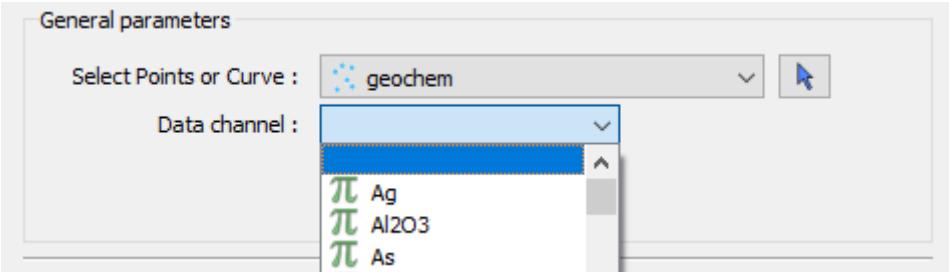

In this example, the object parameter *data\_mesh* is also given for reference.

```
{  
  "data_channel": {  
    "main": true,  
    "association": "Vertex",  
    "dataType": "Float",  
    "label": "Data channel",  
    "parent": "data_mesh",  
    "value": ""  
  },  
  "data_mesh": {  
    "main": true,  
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,  
                "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],  
    "label": "Select Points or Curve",  
    "parent": "data_channel"  
  }  
}
```

(continues on next page)

(continued from previous page)

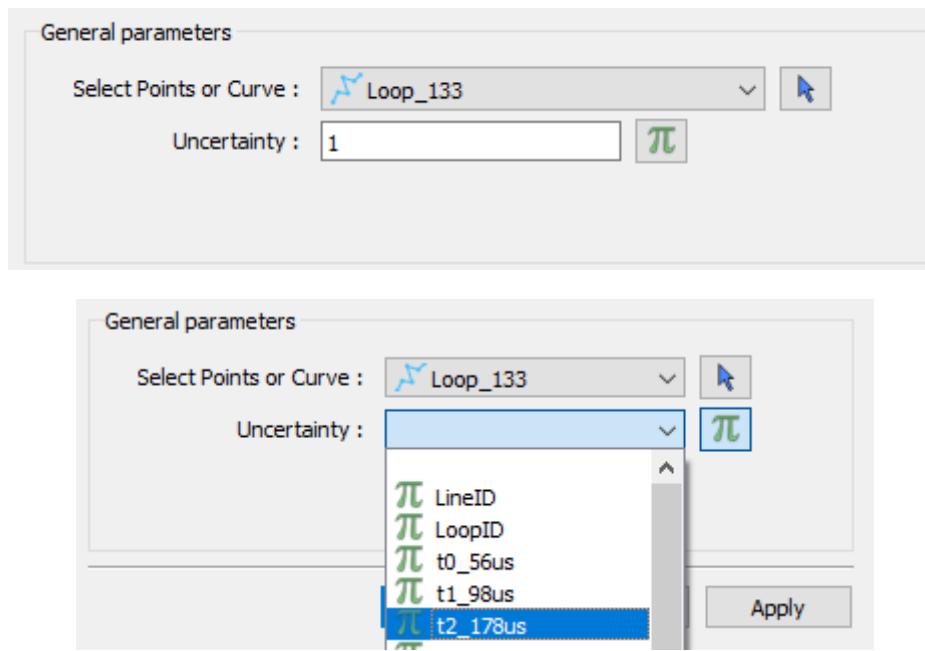

```
"value": ""  
}  
}
```

## Data or value Parameter

In some cases, a parameter may take its data from a Geoscience ANALYST object or simply a `float` value. The use of the member `isValue` and `property` together allows for the UI to switch between these two cases. In the top image, the `isValue` is true, so the `value` member of 1.0 will initially be active. When the icon is clicked, the type of input is switched to the `property` member (bottom image). The `uncertainty_channel` object also depends on the `data_mesh` object. The drop-down selection will filter data from the chosen object that is located on the vertices and is float. The `isValue` is set to false upon export in this case.

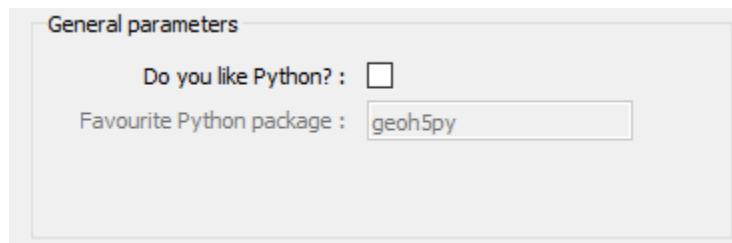

```
{
  "uncertainty_channel": {
    "main": true,
    "association": "Vertex",
    "dataType": "Float",
    "isValue": true,
    "property": "",
    "min": 0.001,
    "label": "Uncertainty",
    "parent": "data_mesh",
    "value": 1.0
  },
  "data_mesh": {
    "main": true,
    "meshType": ["{202C5DB1-A56D-4004-9CAD-BAAFD8899406}" ,
      "{6A057FDC-B355-11E3-95BE-FD84A7FFCB88}"],
    "main": true,
    "label": "Select Points or Curve",
    "value": ""
  }
}
```

## Dependencies on other parameters

Use the **dependency** and **dependencyType** members to create dependencies. The parameter driving the dependency should set **optional** to true or be a *Boolean parameter*. Below are a couple of examples. The first initializes the *favourite\_package* parameter as disabled until the *python\_interest* parameter is checked. The second shows the opposite when the **enabled** member is set to true.

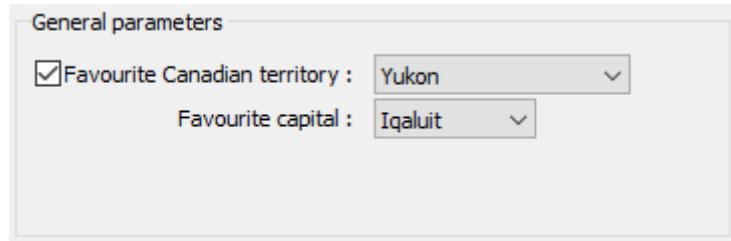

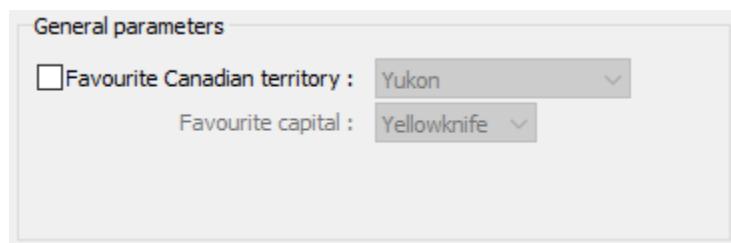

```
{
  "python_interest": {
    "main": true,
    "label": "Do you like Python?",
    "value": false,
    "tooltip": "Check if you like Python"
  },
  "favourite_package": {
    "main": true,
    "label": "Favourite Python package",
    "value": "geoh5py",
    "dependency": "python_interest",
    "dependencyType": "enabled"
  }
}
```

The next example has a dependency on an optional parameter. The **enabled** member is set to false so

that it is not automatically checked. The *city* and *territory* parameters will be enabled when the *territory* checkbox is checked.

```
{
  "territory": {
    "choiceList": ["Northwest Territories",
      "Yukon",
      "Nunavut"],
    "main": true,
    "label": "Favourite Canadian territory",
    "value": "Yukon",
    "optional": true,
    "enabled": false
  },
  "city": {
    "main": true,
    "choiceList": ["Yellowknife",
      "Whitehorse",
      "Iqaluit"],
    "label": "Favourite capital",
    "value": "",
    "dependency": "territory",
    "dependencyType": "enabled"
  }
}
```

## 2.5.5 Tips on creating UIs

- Keep labels concise
- Write detailed tooltips
- Group related attributes
- Don't include the **main** member with every parameter. "Non-main" members are designated to a second page under *Optional parameters*
- Utilize **optional** object members and dependencies.

## 2.5.6 External Links

- JSON Schema
- Universally Unique Identifier (UUID)

## 2.6 Release Notes

### 2.6.1 Release 0.4.0 - 2022/08/26

Major release adding new classes and fixing issues with the DrillholeGroup class.

- Fixes for concatenated DrillHoleGroup
  - GEOPY-598: Implement IntegratorDrillholeGroup class
  - GEOPY-583: Better handling of adding and removing concatenated drillholes and data intervals.
- GEOPY-584: Preserve integer values on IntegerData class.
- GEOPY-548: Allow TextData values on vertices and cells.
- GEOPY-329: API implementation of DrapeModel object class.
- GEOPY-462: Documentation fixes

### 2.6.2 Release 0.3.1 - 2022/08/26

This release addresses issues encountered after the 0.3.0 release.

- GEOPY-608: Check for 'allow\_delete' status before removing.
- GEOPY-600: Fix crash on missing 'Group types' group from project written by ANALYST.
- GEOPY-587: Increase PEP8 compliance after pylint update.
- GEOPY-575: Improve ui.json documentation.

### 2.6.3 Release 0.3.0 - 2022/06/30

This release addresses changes introduced by the geoh5 v2.0 standard.

- Drillhole objects and associated data are stored as Concatenated entities under the DrillholeGroup.
- Use of context manager for the Workspace with options for read/write mode specifications added.
- Implementation of a SimPEGGroup entity.

### 2.6.4 Release 0.2.0 - 2022/04/18

- Add MT, tipper and airborne time-domain survey objects.
- Add ui.json read/write with validations
- Bug fixes and documentation.

### 2.6.5 Release 0.1.6 - 2021/12/09

- Fix StatsCache on value changes.
- Fix crash if data values are None.
- Clean up for linters

### 2.6.6 Release 0.1.5 - 2021/11/05

- Fix for copying of direct-current survey.
- Fix documentation.

### 2.6.7 Release 0.1.4 - 2021/08/31

- Add direct\_current survey type and related documentation.
- Fix for drillholes with single survey location anywhere along the borehole.
- Fix for entity.parent setter. Changes are applied directly to the target workspace.
- Improve Typing.
